The radius of significant relationships expands as adolescents enter new roles and new settings. During early adolescence, the peer group becomes more structured and organized than it was previously and peer group membership becomes much more salient. Dyadic (two-person) friendships become an increasingly important source of social support, and the quality of these friendships changes. In addition to dyadic friendships, adolescents form small groups of friends, sometimes referred to as *cliques*, and in most communities they also become identified with a larger constellation of teens who have a common social identity, usually referred to as a *crowd*. The processes of selection and socialization help explain how boundaries are formed around peer groups, and how membership in peer groups shapes individual attitudes and behaviors. Parents continue to be an important source of reassurance and support for many adolescents. However, the period is characterized by strong desires to find membership and acceptance among peers. Within this context, adolescents seek like-minded peers and are open to peer influence.

OBJECTIVE 6 Explain the psychosocial crisis of group identity versus alienation, the central process through which the crisis is resolved, peer pressure, the prime adaptive ego quality of fidelity to others, and the core pathology of isolation.

The crisis of group identity versus alienation involves a potential tension between the *I* and the *We*, the desire to feel meaningfully connected to a valued group and, at the same time, to have an authentic, autonomous sense of self. A positive sense of group identity provides confidence that one is meaningfully connected to society, has a cognitive map of the characteristics of the social landscape, and the skills or tools to navigate the terrain. Perceiving oneself as a competent member of a group or groups is fundamental to one's self-concept as well as to one's willingness to participate in and contribute to society. Three cognitive capacities are needed for an adolescent to establish a group identity: (1) group representations, the conceptualization and labeling or classification of groups; (2) group operations, the processes through which groups are formed, maintained, or dissolved; and (3) reflective thinking about groups, an ability to analyze the array of groups and their relationship to one another. The actual formation of a group identity requires four types of experiences: (1) categorizing people into groups and recognizing the distinguishing features that define members, (2) experiencing a sense of history as a member of a group, (3) having an emotional investment in the group, and (4) detecting the social evaluation of one's group and its relation to other groups. Issues associated with ethnic identity are reviewed—an aspect of group identity that may become more salient for some adolescents than for others.

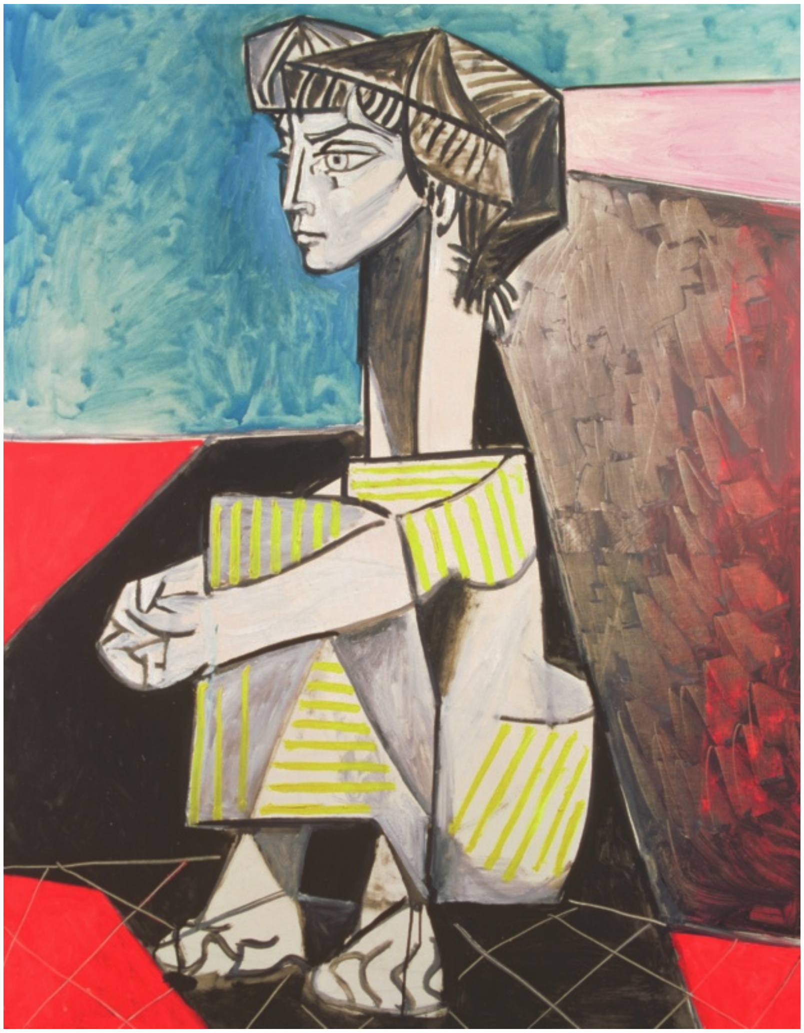
In the process of resolving this conflict, most adolescents experience moments of alienation, a sense of separateness and disconnection, out of which can grow a new personal confidence or a deep well of resentment and rage. Alienation can be viewed as deriving from dilemmas associated with issues of common identity, common bond, or both. The central process of peer pressure refers to demands for conformity to group norms and a demonstration of commitment and loyalty to group members. Peer pressure can be experienced as oppressive or very subtle. The threat of peer rejection may push those adolescents who lack confidence in their own worth to violate essential values in the pursuit of acceptance. The prime adaptive ego quality, fidelity to others, is a capacity to freely pledge one's loyalty to a group and to sustain one's faithfulness to the promises and commitments one makes to others. Fidelity to others produces the sentiments that are necessary to preserve small groups and larger communities. The core pathology, dissociation refers to a sense of feeling removed and separate, withdrawal from others, and an inability to experience the bond of mutual commitment. It reflects a tendency toward social distancing and a reluctance to make the kinds of commitments to others that are required for the establishment and maintenance of enduring friendships and group memberships.

OBJECTIVE 7 Apply your understanding of developmental issues of early adolescence to an analysis of factors that account for patterns of adolescent alcohol and drug use.

Although alcohol and drug use among teens have declined from their recent high levels of the 1990s, they continue to be a major source of health and safety risks. Almost half of American high school students have tried an illegal drug in their lifetime. High concentrations of alcohol in the body it can cause death by suppressing breathing, an outcome that may occur after chugging large quantities of alcohol, a practice that is sometimes included in certain adolescent initiation rites and drinking games. Two other situations in which alcohol use has potentially lethal consequences are the use of alcohol in combination with other drugs, especially barbiturates, and its use in combination with driving. The risks associated with underage drinking are reviewed. Alcohol use is linked to other developmental tasks of early adolescence, including cognitive, emotional, and social factors. Alcohol misuse takes place in a context of family, peer, school, and community forces that may constrain or encourage drinking and drunkenness.

CASEBOOK

For additional case material related to this chapter, see the case entitled "The Early Bloomer," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry Meyer, and Brenda J. Lohman, pp. 120–123. The case focuses on the challenges of early maturing for girls and how pubertal timing influences social relationships.



Portrait of the Artist's Wife, Jacqueline Kneeling, 1954 (oil on canvas), Picasso, Pablo (1881-1973)/Private Collection/Giraudon/The Bridgeman Art Library

Engaged in the active resolution of the identity crisis, young people make commitments that will shape the structure of their adult lives. In this portrait, Picasso suggests the balance, focus, and purposefulness of a young woman who is striving to achieve a sense of personal identity.

LEARNING OBJECTIVES

1. Explain the concept of autonomy from parents and examine the conditions under which autonomy is likely to be achieved.
2. Summarize the development of gender identity in later adolescence. Analyze how the components of gender-role identification that were relevant during the early-school-age period are revised and expanded.
3. Investigate the maturation of morality in later adolescence, with special focus on the role of new cognitive capacities that influence moral judgments and the various value orientations that underlie moral reasoning.
4. Trace the process of career choice, with attention to education and gender-role socialization as two major influential factors.
5. Define and describe the psychosocial crisis of later adolescence, individual identity versus identity confusion; the central process through which this crisis is resolved, role experimentation; the prime adaptive ego quality of fidelity to values and ideals; and the core pathology of repudiation.
6. Examine some of the predictors and consequences of dropping out of college and hypothesize how dropping out of college may influence development in later adolescence.

Chapter Summary

— **CASE STUDY** Growing Up Through Divorce: A College Student's Insights —

A 22-year old male wrote this account as part of an assignment in a college course on interpersonal relationships. Students who self-identified as coming from families of divorce were asked to write on the pros and cons of divorce for all concerned, as well as how the divorce affected them and their siblings.

As the years went by after the divorce the emotional trauma still lingered and I never felt like I was very close with my parents. The responsibilities required of me living in the household of a single parent were a tough initial adjustment, but I feel I am a much better person because of it. I feel a sense of accomplishment and confidence in working to keep our household functioning for so many years. I also have been able to pinpoint one of my personality traits: the feeling that I should always be pleasing people. For most of my teen years my mom would get upset when I wouldn't meet her emotional needs; so I worked to counter that by always trying to please her and make her happy in order to prevent her from being upset, which always stressed me out.

Recently my dad has remarried, and it has been a very happy time for all of us. The fact that he is in a stable, loving relationship is just a huge ease to my mind. The weeks after the wedding I noticed a difference in my psyche. I really felt a lot of closure on my parents' divorce. I had never realized the weight my subconscious feelings about the divorce had on my over-all mental health.

Coming to college was a very positive experience for me. It gave me some perspective on the family I have come from, a family I love very much; but for my own mental health, I needed some distance from them. There is a lot of significance in my parents remarrying—those events have brought closure on my lingering feelings of loss from the divorce. (Harvey & Fine, 2004, p. 81)

CASE ANALYSIS Using What You Know

1. Describe how divorce propels this young man to deal with issues that require more responsibility and maturity than many of his age-mates. How typical do you think this is? What does it suggest about the diversity of adult-like roles that young people enact in later adolescence?
2. Evaluate the quality of the parent–child relationship that is described in this case. How well is this young man working on balancing his feelings of autonomy and closeness?
3. Generate ideas about how helping with household responsibilities as a teenager may be of value in adapting to the college environment or for establishing a sense of self-sufficiency.
4. List some ideas about how the college environment might enhance mental health and a sense of well-being in later adolescence.

There is general agreement among human development scholars that the years from about 18 through 24 are a distinct stage of development, separate from early adolescence and from early adulthood. Studies from a variety of industrialized countries confirm that young people in these societies have characteristics that distinguish them from younger teens, especially advanced cognitive reasoning abilities, intensive personal identity exploration, a feeling of being somewhere in between childhood and adulthood, and a preoccupation with future possibilities. These developmental capacities are unfolding in the context of significant societal conditions including a prolonged period of education and training before entry into and investment in an occupational role, delayed age at marriage and childbearing, and difficulties becoming financially self-sufficient (Arnett, 2006; Sirsch, Dreher, Mayr, & Willinger, 2009). Pathways into adulthood are stretched out and diverse (Coté, 2014).

What should we call this stage of life? Despite a growing enthusiasm in the field of human development to refer to this as the stage of emerging adulthood, we prefer the term later adolescence for the following reasons:

1. Adulthood, a status that is socially and culturally constructed, is becoming an increasingly elusive state, difficult to define or achieve. The adult transition might be considered to be completed when three or more of the following five criteria have been achieved: leaving home, completing one's education, becoming financially independent, getting married, and, for most, having children (Furstenberg, 2010). FIGURE 10.1 ▶ provides a comparison of the percentage of men and women who completed all five of these markers of adult status by age 20, 25, and 30 in 1960 and 2000. In 1960 this transition into adulthood was very unusual for men and women aged 20, but common for young men aged 25 and normative for young women aged 25. By 2000, it was no longer normative for all five markers of adult status to be achieved by men or women at age 25 or 30. These data illustrate that adulthood is not emerging in the ages of 18 to 24 years, but in fact, is further away than it was 55 years ago.

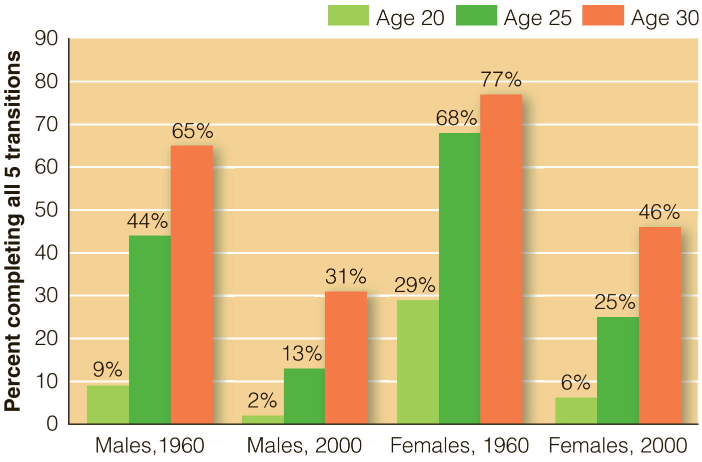

FIGURE 10.1 ▶ THE PERCENTAGE COMPLETING FIVE CRITERIA OF THE ADULT TRANSITION, 1960 AND 2000, BY AGE AND GENDER

Source: Data are from the Integrated Public Use Microdata Series extracts (IPUMS) of the 1960 and 2000 U.S. Censuses. Men are defined as financially independent if they are in the labor force; women are defined as financially independent if they have completed all transitions except employment in the labor force. Table reprinted, with permission, from *Between Adolescence and Adulthood: Expectations about the Timing of Adulthood* (Working Paper No. 1), by F. F. Furstenberg, S. Kennedy, V. C. McLoyd, R. G. Rumbaut, and R. A. Settersten, (2003), Philadelphia: Network on Transitions to Adulthood. Used by permission of Frank Furstenberg, Jr.

2. In contemporary industrialized or post-industrialized countries, young people are enrolling in postsecondary education at greater rates than ever before. This includes associates degree, bachelor's degree, and professional degree programs. The student status, which by definition is transitional as one moves toward a level of new knowledge and expertise, has been extended. Typically the student status delays full-time entry into the labor market and fosters a prolonged period of temporary residential identification with a community.
3. The average age at first marriage is approaching 30. Although the majority of young people in the age range 18 to 24 are sexually active, their relationships are temporary. Relatively few young people in the age range 18 to 24 are involved in relationships that they expect will result in marriage.
4. The economic recession of 2008–2009 resulted in a growing number of young people who were out of work, underemployed, or working at jobs that were viewed as temporary. Among high school graduates ages 17 to 20, 19 percent are unemployed and 37 percent are underemployed (Davis & Kimball, 2015). The percentage of young people in this age group who can support themselves has declined even further than it was in 2000.
5. Close to 60 percent of people ages 20 to 24 years who are not married live with their parents. One recent change in the U.S. health policy was a provision to allow young people to remain on their parents' health insurance policies until age 26. These are just two indications of the continued financial dependence of young people on their parents.

The prospects of making a behavioral, psychological, or social transition into adulthood is not emerging in the age period of 18 to 24 years. We prefer the term later adolescence because it connotes a process of continued growth and maturation prior to adulthood. The executive decision-making capacities of the frontal cortex are still maturing, suggesting that later adolescents have new abilities for reflection, problem solving, and planning, but these capacities are not fully developed (Cohen et al., 2016). For many, this is a period of exploration, experimentation, and self-development. As one author described it, "between the late teens and late 20s...young Americans experience their 'odyssey years,' a time of wandering on the path to maturity" (Boonstra, 2009, p. 13).

An estimated 15 percent of youth ages 18 to 24 are disconnected; they are not in school, and they are not employed. Some are in jail, others are homeless or disabled, and others have been released from foster care but are having difficulty achieving independent lives (National Kids Count, 2016).

Later adolescence is a time of fewer constraints and greater self-determination than early adolescence. Young people ages 18 to 24 do not have to be in school even though many are. New legal rights and privileges become available. Life paths become increasingly divergent as young people make choices and pursue their goals. But, by and large, these paths are experimental and temporary, reflecting the flexibility of the stage and the lack of urgency to make long-term commitments.

Later adolescence is characterized by a heightened sensitivity to the process of identity development. Personal identity is developed as an individual struggles to answer the questions, "What is the meaning of my life? Who am I? Where am I headed?" Most young people are cognitively complex enough to conjure up alternative scenarios about their own future, including possible kinds of work and various meaningful relationships. They struggle with the uncertainty of having to choose their own life's directions. This period is often characterized by a high level of anxiety. Even though most young people are energetic and capable, they are also troubled by the lack of certainty about their future. Some worry whether they will be able to succeed in a chosen direction; others may be anxious because they do not even know what direction they wish to take.

FURTHER REFLECTION: *Assess the distinguishing features of later adolescence as compared to early adolescence. Where do you place yourself on the ladder of development from early adolescence to adulthood? Why?* ●

Developmental Tasks

Autonomy from Parents

OBJECTIVE 1 Explain the concept of autonomy from parents and examine the conditions under which autonomy is likely to be achieved.

Achieving a psychological sense of autonomy from one's parents is a multidimensional task that is faced gradually over the course of later adolescence and early adulthood. As illustrated in the opening case, young people enter the period of later adolescence carrying with them complex mental representations of their relationships with family members, including feelings of obligation, emotional closeness or distance, and some preoccupation about their parents' expectations for them. **Autonomy** from parents is the ability to regulate one's behavior and to select and guide one's decisions and actions in order to achieve meaningful personal goals without undue control from or dependence on one's parents. Autonomy suggests that decisions and behaviors are guided by personal will; they are voluntary rather than imposed or controlled by others (Ryan & Deci, 2000).

Autonomy is not the same as rejection, alienation, or physical separation from parents. Rather, it is an independent psychological status in which parents and children accept each other's individuality. Many areas of similarity between parents and children may provide bonds for a continued close, supportive relationship into adulthood. However, those bonds are re-created in later adolescence and early adulthood through a process of self-definition. Adolescents who achieve autonomy can recognize and accept both the similarities and the differences between themselves and their parents while still feeling love, understanding, and connection with them. It is not uncommon for later adolescents to experience a strengthening of their family identity and their sense of obligation to their family in later adolescence, recognizing the importance of family experiences to the way they think about themselves, a feeling that their parents value their ideas and opinions, and a sense of mutual responsibility and care (Tsai, Telzer, & Fuligni, 2013).

Autonomy may refer to independence of behavior, thoughts, and emotions (Steinberg, 2013). Much of the psychosocial development that has occurred in childhood and early adolescence can be understood as preparing for behavioral independence from one's parents. Such skills as dressing oneself, handling money, cooking, driving a car, reading, and writing have been mastered. Many of these skills are incorporated into the concept of activities of daily living (ADLs), a measure that is used to assess the self-sufficiency of older adults. Although it is easy to take these skills for granted, they are essential for someone who is living independently. The physical maturation that has taken place also contributes to the possibility of autonomy. Daily survival requires physical strength, coordination, and endurance—qualities that accompany the physical maturity of adolescence.

Beyond these physical requirements, autonomy involves a psychological sense of confidence about one's unique point of view and an ability to express opinions and beliefs that may differ from those of one's parents (Herman, Dornbusch, Herron, & Herting, 1997). In early school age, the process of identification and the accompanying internalization of parental values allow the young child to function with a sense of what is appropriate behavior. In early adolescence, the child's ability to emerge from the intimacy of the family may also be promoted by a growing involvement with the peer group. In early adolescence, a young person's autonomy is expressed in personal preferences and tastes that are considered legitimate domains for decision making. In later adolescence, a young person's cognitive maturity provides problem-solving abilities, the ability to consider multiple perspectives and to evaluate information from multiple sources, and a capacity to plan for the future, all of which support new levels of autonomous reasoning about important life choices. As later adolescents become more autonomous in thought, they are able to reflect upon their parents' opinions and advice and to set these views next to their own as well as the views of peers or other mentors or authorities in order to decide what makes sense for them.

The concept of **differentiation**, a term drawn from family systems theory, has been associated with emotional maturity and a healthy emergence of individuality. Differentiation is the extent to which a social system encourages intimacy while supporting the expression of differences (Bomar & Sabatelli, 1996). Within the family context, identity exploration is facilitated by an open exchange of ideas and a certain level of challenge. Adolescents must have opportunities to express their separateness within the boundaries of the family. They must feel that their parents accept and understand their need to have distinct opinions and views. This takes place as parents support their child's quest for autonomy and encourage their child to express new ideas and differing points of view without making them feel guilty when they disagree (Best, Hauser, & Allen, 1997). Adolescents who experience high levels of parental control and frequent exposure to parental conflict are likely to have difficulties achieving a comfortable sense of autonomy (Taylor & Oskay, 1995; Oudekerk, Allen, Hessel, & Molloy, 2015). In contrast, well-being is higher among college students who perceive their parents as supporting their autonomy (Ratelle, Simard, & Guay, 2013; Van der Giessen, Branje, & Meeus, 2014). Ideally, individuality is achieved in a context of mutual caring and emotional support. A secure attachment to parents, based on a perception of them as committed to their child's well-being, is essential for growth toward independence (Buhl, 2007; Palladino-Schultheiss & Blustein, 1994; Perosa, Perosa, & Tam, 1996).

In response to a question about drinking and partying at college, one student explained how her parents' support influenced her decisions.

> I was very open with my parents before, my mom especially. We had a talk like the day before I moved in and both my parents told me that they don't mind if I just like try. They know I am curious. They told me that I know my limits and I do know. Like I know, they always told me like I'm pretty responsible so I know when too far is too far. So I feel like if I was to just try it once, I would know not to go crazy, because I know the consequences of it. So I just feel like they trust me a lot so that's kind of, it's been really good that I know that they trust me. (Adams, Kisler, Vaccaro, & Newman, 2013)

The meaning a young person gives to achieving autonomy from parents varies depending on personal, family, and cultural values, such as commitment to education, financial independence, and marriage. For example, some cultural groups are more accustomed to living in multigenerational families and place great value on the filial bond between children and their parents. Parents in these cultures may be more comfortable with the idea of having their later adolescent children living in their home without paying rent, and the children may perceive it as part of their obligation to stay near their parents and grandparents in order to provide social and instrumental support. In contrast, in some cultures, families expect their later adolescent children to achieve residential separateness. They may expect that children ages 18 to 24 who are living at home will contribute to the cost of housing.

Danielle Donders/Moment/Getty Images

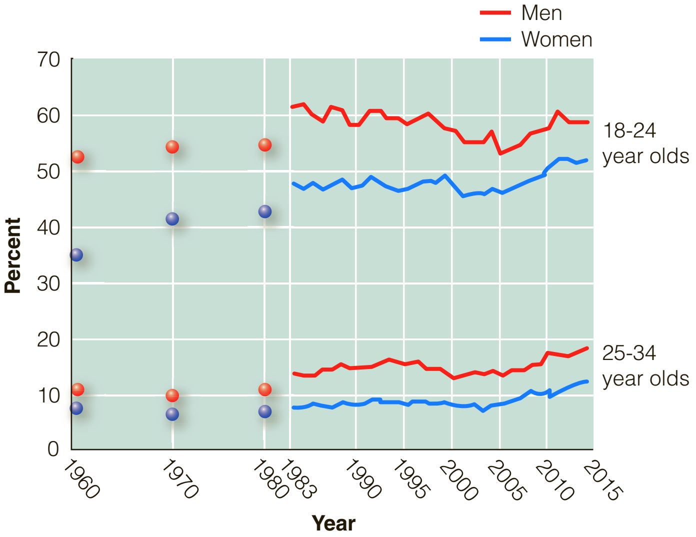
Families have ways of remaining close while still giving their later adolescent children room to express their individuality.

As illustrated in the opening case, paths toward autonomy are influenced by the family context. The young man in the case tells us that as a teenager he had taken responsibility for many aspects of family life, preparing him for the instrumental aspects of autonomy. His experiences focus more on his emotional attachments and the opportunity to gain some distance from feelings of confusion, obligation, and loss. Children living with their two biological parents are likely to leave home later than are children living in a stepfamily. Children growing up in families with few financial resources are likely to have to assume responsibilities for their family's household tasks, sibling care, and economic needs at a younger age, thereby accelerating their sense of self-sufficiency (Benson & Elder, 2011). Three components of achieving autonomy from parents are discussed in the following sections: leaving home, attending college, and self-sufficiency.

Autonomy and Leaving Home

Living away from one's parents' household may be a symbol of independence; however, it is not as readily achievable in the age range from 18 to 24 as it was in the past. Before about 1960, marriage was the most traditional reason for moving to a new residence other than leaving temporarily for college or the military. Since that time, however, the median age at marriage has increased; in 2015, 87 percent of those in the age range from 20 to 24 have never been married (U.S. Census Bureau, 2015b). More than half of these later adolescents consider their parents' home as their permanent residence (U.S. Census Bureau, 2015c) (see FIGURE 10.2 ▶).

Parents and adolescent children have different views about the age at which children are expected to leave home. Parents tend to expect children to leave home at an older age—more closely tied to the expected age of marriage—than do adolescent children. Also, parents expect daughters to live at home longer than sons. However, these differences are not reflected in the expectations of the adolescents themselves. Thus, this issue is a potential source of family conflict. Family structure is also associated with the age of leaving home. Children in single-parent families and girls in stepfamilies leave at an earlier age (Cooney & Mortimer, 1999).



Note: Unmarried college students living in dormitories are counted as living in group quarters in decennial data but as living in their parental home in CPS data.

FIGURE 10.2 ▶ PERCENTAGE OF YOUNG ADULTS LIVING IN PARENTAL HOME

Source: U.S. Census Bureau, Decennial Censuses, 1960 to 1980, and Current Population Survey, Annual Social and Economic Supplements, 1983 to 2015.

Economic factors and social norms play a significant role in the timing of leaving home. A child's ability to live away from home may depend on whether the family is willing and financially able to provide support during this period. This, in turn, depends in part on the family's values and the later adolescent's values. For example, many families are strongly committed to having their children complete college and are willing to provide financial support while the child is away at school. However, if the child gets married while still in college, some families may feel that their financial obligation to support the child is over.

Some parents are willing to support their children who are away from home if the child is in college but not willing to provide support if the child wants to live away from home but not attend school (Goldscheider, Thornton, & Yang, 2001). Imagine that, after 1 or 2 years of college, a child wants to move to a new city and seek opportunities in the entertainment industry. Some parents might encourage this path toward self-discovery; others might consider it risky or frivolous. When children and parents disagree about the appropriate path toward self-reliance and adulthood, parents may be unwilling to provide the financial resources that would make this level of autonomy possible.

What is the relationship of later adolescents' living arrangements to their well-being? Do young people who continue to live at home with their parents have the same sense of well-being and life satisfaction as young people who live in some type of group situation with other friends or who live independently? There are some conflicting views about this. Some studies show that later adolescents who live with peers or on their own have a more adult-like view of themselves and get along better with their parents than those who live with their parents (White, 2002). Other studies show that later adolescents who have a good relationship with their parents are more likely to live with them for a longer period (Lanz & Tagliabue, 2007).

When there is a stepparent involved or frequent conflict with parents, later adolescents may feel pushed out into independent living. A study of Belgian later adolescents examined the relationship of three types of living arrangements to well-being: living at home with parents, living with other students but returning home frequently, and living independently with a partner or alone. The most important factor was the young person's sense that the living arrangement was of their own choosing. In addition, later adolescents whose parents supported their autonomous decision were most confident about their decision and had the greatest sense of well-being, regardless of whether they lived at home with their parents, with friends, or on their own (Kins, Beyers, Soenens, & Vansteenkiste, 2009).

Autonomy and the College Experience

Going away to college is an intermediate step between living at home and establishing a separate permanent residence. The mere act of going to college does not in itself bring a sense of leaving home or of psychological autonomy from one's parents. In fact, most students do not go far from home when they enter college as freshmen; over half live 100 miles or less from home. Fifteen percent of freshmen continue to live at home while they attend college

Michael Newman/PhotoEdit

Students who go away to college use their group identity skills to form new relationships while creating a physical environment that preserves a connection to family, friends, and home.

and 18 percent say that enrolling in a college close to home was a very important factor in their choice of which college to attend (Eagan et al., 2015). The likelihood of attending college close to home depends in part on the number of colleges and universities in one's home state. In states like Utah, Arizona, and California, close to 90 percent of students attend college in state (Guo, 2015).

Most freshmen still request and receive both emotional and instrumental support from their parents. In an ongoing study of belonging among college freshmen, most students we have interviewed report frequent contact with their parents during the first few weeks including texting, emails, and phone conversations. Students often describe their sense of belonging by saying that the campus feels "like home." Many students hold on to their connection to family through the bits and pieces of home that they use to decorate their dorm rooms.

Some college-age students are more ready than others to embrace the demands for new levels of independence and responsibility. College freshmen express a variety of attitudes that suggest different views about their desire to be independent from their family. Of students entering college in the fall of 2015, 18 percent said that a very important reason for deciding to go to a specific college was that their parents wanted them to attend; 18 percent said that it was very important to live near home (Eagan et al., 2015). As they enter college, students differ markedly in how much work they have already done toward achieving autonomy from their parents, how much they desire autonomy, and what evidence they use to determine whether they have achieved autonomy.

Similarly, parents differ in how ready they are to support and encourage their child's autonomy. Many parents experience pangs of separation distress as their children leave for college. They know that their child will be entering a new period of self-discovery and maturation, and that their relationship will change. Despite feelings of sadness about separation, they are able to step back and let their child experience a new level of independence. Whereas most parents are able to encourage and support their child's emerging autonomy, some have been given the dubious label of "helicopter parents," a term that suggests over-parenting. These parents may convey their own anxiety about their child's well-being through excessive levels of involvement, control, and problem solving. They engage in inappropriate levels of assistance and direct intervention on behalf of their children, either directly with their children or with advisors, faculty, and/or administrators. The impact of this "hovering" approach is to undermine the child's self-confidence and increase the young person's feelings of anxiety and stress (Segrin, Woszidlo, Givertz, & Montgomery, 2013).

Revision of Attachment to Parents

The experience of entering college focuses new attention on the changing quality of the attachment relationship between college students and their parents. Students who live at college are more likely to rely on the mental representations of their attachment figures, whereas students who live with their parents continue to be involved daily with concrete interactions. Issues of autonomy and control, establishing new guidelines and limits related to participation in family life, involvement in relationships with peers, and management of time and money are resolved in the absence of direct input from parents for most students who live at college, but these decisions continue to involve parental input for students who live at home.

For students who live on campus, preoccupation with thoughts and concerns about their parents tend to diminish over the course of the first semester while new relationships form and confidence in their independent decision making builds. The attachment scheme or representation, rather than the actual interactions with parents, is modified. Many students who attend college away from home begin to have more positive thoughts and feelings about their parents. At the same time, they begin to detect a new level of confidence and respect from their parents, who appreciate that their children are managing to take on new responsibilities and to make good decisions on their own.

> Over the past year I have become very close with my dad. Before college there was a definite parent–child relationship with my father. Now he is more like a mentor or friend. Overall, the relationship between my parents and I has been a growing mutual respect. (Arnett, 2004a, p. 215)

In other cases, going to college represents a move toward upward mobility and a decision to seek a life path quite different from one's parents. Even when parents are supportive of a child's college attendance, the experiences of college may introduce their child to new ideas, values, and interests that create conflict. Parents who have not attended college may not understand what their child is doing, why it is important or valued, or how their child's involvement in certain classes or campus activities will lead to economic betterment. For some, this distance is gradually bridged as parents become familiar with their children's lives, and children become more skilled at giving parents ways of understanding what they are doing. For others, as in the case of Mary, the distance widens over time:

> I go home, we talk about the weather, talk about people in the family, people in the neighborhood. . . . The stuff I would like to talk about, [my mother] can't. She doesn't understand it. Stuff she'd like to talk about I think would be incredibly boring. . . . I learned very early on that they couldn't discuss [school]. To try to discuss it with them would be very frustrating to me and embarrassing for them. . . . I realized I had far educated myself past my parents. (Roberts & Rosenwald, 2001, p. 102)

The relationship between emotional closeness and living at home is culturally shaped. For example, in the United States, later adolescents who live at home and have frequent daily interactions with their parents tend to be *least* close to them. In comparison, studies of European later adolescents find that young people who live at home are quite happy with their living arrangements, find their parents to be an important source of emotional support, and experience considerable autonomy in the context of their parents' household (Arnett, 2000). The **Applying Theory and Research to Life** box Attachment and Identity Formation provides more detail on the relationship of parental attachment to identity formation in later adolescence.

The delay in age at marriage also has implications for the revision of the **parental attachment** relationship. When the majority of young people in the 20 to 24 age range were married, it was normal to expect that some of the emotional investment in one's family of origin would shift to the new intimate marital bond. Thus, emotional distancing from one's parents made sense in the context of forming a culturally approved marital commitment. Today, many young people have deeply valued love relationships, but they are not married and are not ready to make lifelong commitments to these relationships. This results in lengthening the period when both children and parents may feel that the child's primary emotional attachment is to the family of origin.

Autonomy and Self-Sufficiency

Despite the variety of life paths and demographic characteristics of those in the period of later adolescence, most young people can recognize when they have achieved a sense of autonomy from their parents. One important underlying theme is a sense of **self-sufficiency**, expressed by making independent decisions, taking responsibility for one's actions, and achieving a degree of financial independence.

The expression of self-sufficiency can be particularly challenging for college students with disabilities. In the transition to college, students with disabilities leave behind the structures in place in elementary and secondary school that are associated with the identification, assessment, and development of educational plans to support and accommodate their needs. The process of disclosing one's disability and receiving appropriate accommodations rests squarely on the student's shoulders in the post-secondary environment. In one national study, only 28 percent of students who had received accommodations in high school said that they informed their postsecondary institution of their disability (Newman et al., 2011). Yet, it is known that **self-advocacy**, "the ability to communicate one's needs and wants and to make decisions about the supports needed to achieve them" is closely related to college persistence and success (Adams & Proctor, 2010). In one qualitative study, students with disabilities described a variety of ways that they learned self-advocacy skills from family members. Once at college, these students found that they had to adapt their approach in the new environment.

> Before I had my parents to help me with meetings . . . and this time I was all on my own . . . I had to . . . self-advocate, you know? But that's obviously a skill you need for life and that's a skill you learn in college. So I was happy I was doing that. But, that was just overwhelming because I [had] to go in to talk to my teachers and make that first move. (Daly-Cano, Vaccaro, & Newman, 2015)

Other aspects of self-sufficiency relate to financial needs. In one study, researchers asked students and their parents to select a question from a survey about autonomy and write why they might disagree about this issue. One of the items was, "My parents will give me money when I ask for it." The following responses illustrate the point of view of a student who would like to be as financially self-sufficient as possible, and the point of view of a parent who wants her daughter to know that there are some limits to the kind of support she can expect (Kenyon & Koerner, 2009, p. 307).

> 18-YEAR-OLD FEMALE: I think one of the things we would disagree about is money. My father is helping me with rent, and both of my parents are helping me financially, when I need it. They want me to come to them if I need money, but I want to be able to do things on my own, without having to run to mommy or daddy whenever I need money. They don't mind helping me out, but I would like to try and get by on my own as much as I can. It will be easier when I get a job.
>
> 44-YEAR-OLD MOTHER: She will think that I will give her money for 99% of the things that she thinks is important and that is not going to be the case. I will give her money when she needs it for the important things that you need to live on or with. No shopping sprees for the heck of it!

Although few college students who are enrolled full time expect to work full time, roughly 50 percent of college students who are enrolled full time are also employed. Data from six countries including the United States and Canada show that over the past 20 years there has been a decline in the percentage of later adolescents who are able to support themselves as defined by wages and salary above 50 percent of the national adjusted disposable personal income for their country (Bell, Burtless, Gornick, & Smeeding, 2007). The median annual income for 20- to 24-year-olds who were not in school was *lower* in 2012 than in 2000 for all levels of education (Federal Interagency Forum on Child and Family Statistics, 2014). In 2009, 21 percent of those in the 18- to 24-year-old age range had incomes below the poverty level. As shown in FIGURE 10.3 ▶, this rate varied by sex and level of educational attainment (Aud, KewalRomani, & Frohlich, 2011). These data help to explain the pattern of delays in self-sufficiency and the postponement of an independent lifestyle.

APPLYING THEORY AND RESEARCH TO LIFE

Attachment and Identity Formation

Identity formation is usually viewed as a process that requires young people to distance themselves from the socialization pressures and expectations imposed by parents and other family members. To achieve an individual identity, one must create a vision of the self that is authentic—a sense of having taken hold of one's destiny in an effort to reach goals that are personally meaningful. Yet research has demonstrated that the quality of family relationships contributes significantly to a young person's ability to achieve a personal identity (Allen, 2008).

The relationship between close parental bonds and identity achievement can be compared to the way that a secure attachment in infancy supports a willingness to explore the environment. Securely attached infants will move away physically from their caregiver, confident that the caregiver will be available when they are in need of help. For later adolescents, autonomy-seeking behaviors can be interpreted as a more advanced form of the exploratory activities observed in infancy. Later adolescents who have a secure relationship with their parents and who are comfortable in loosening these ties can begin to explore the ideological, occupational, and interpersonal alternatives that become the content for their own identities.

Attachment to parents in later adolescence and adulthood has been measured using the *Adult Attachment Interview* (AAI), which asks participants to describe their relationship with their parents when they were younger, including specific memories of that relationship; recall incidences of distress in the relationship; and discuss factors that have influenced their relationship (George, Kaplan, & Main, 1996; Hesse, 2008). The interview is then coded to characterize the attachment state of mind as (1) *autonomous*, reflective of an open, coherent narrative about the parent–child relationship; (2) *dismissive*, reflective of minimizing the importance of the parent–child relationship, inability to recall many details, and a tendency to idealize one's parents; or (3) *preoccupied*, reflective of continuing anger toward one's parents and a confused, vague, or passive narrative (Bernier et al., 2004). Interviews with students at the beginning and end of the first year of college found that the preoccupied students had the most difficulty adapting to college and actually did worse with respect to adjustment and grades as the year went along. These students had the greatest difficulty transferring their emotional investment from parents to peers, even if that investment was negative (Bernier et al., 2004).

Students who have a positive attachment to their mothers are more likely to have an achieved identity and are less likely to be in a moratorium or identity-confused status than are students who have insecure, mistrustful relationships with their mothers. On the other hand, those whose attachments are insecure show a greater tendency to experience identity confusion and are more vulnerable to experiences of depression (Agerup, Lydersen, Wallander, & Sund, 2015; Benson, Harris, & Rogers, 1992).

By the time young people reach later adolescence, those who are securely attached to their parents are confident about parental affection and support. They can receive and implement parental advice insofar as it seems useful and practical. At the same time, they trust in their own worth and their ability to make decisions (Carlson, 2014). Later adolescents may make a point of *not* seeking parental support, but in a secure relationship, they know that help is available if needed. By imposing emotional distance and achieving greater self-reliance, later adolescents are able to reach a more objective evaluation of their parents as figures for identification and, thereby, to create the needed space for the emergence of their own identity (Kobak & Madsen, 2008).

A secure parental attachment supports identity formation in the following ways:

- It fosters confidence in the exploration of social relationships, ideologies, and settings.
- It establishes positive expectations in regard to interpersonal experiences outside the family.
- It fosters the formation of group identities apart from the family, thus providing a transitional context for work on individual identity.
- It provides a basic layer of self-acceptance, permitting the young person to approach the process of identity formation with optimism.

Critical Thinking Questions

1. Analyze how the typology of *preoccupied* attachment in adolescence or adulthood corresponds to the attachment styles described in the section on infant attachment in chapter 5. What do you think the mental representations of parents of the *preoccupied* later adolescent are like? Hypothesize about why these students have difficulty adjusting to college.
2. Explain the relationship between a secure attachment in infancy and an autonomous attachment in later adolescence. Describe the kinds of behaviors and attitudes you would expect to see among later adolescents who have an autonomous attachment style.
3. Infer from your readings how the formation of an avoidant, resistant, or disorganized attachment in infancy would relate to work on identity in later adolescence.
4. Create a matrix that compares the benefits and costs of living at home with parents and living on campus with respect to identity formation and self-acceptance.
5. Describe how cultural differences with regard to the values of independence and interdependence might influence the process of attachment and achieving autonomy from parents in later adolescence.
6. Imagine that you were asked to advise families about the optimal balance between autonomy from parents and connection to parents during the college years. What should parents and students do to try to achieve this balance? What should colleges and universities do to help families achieve this balance?

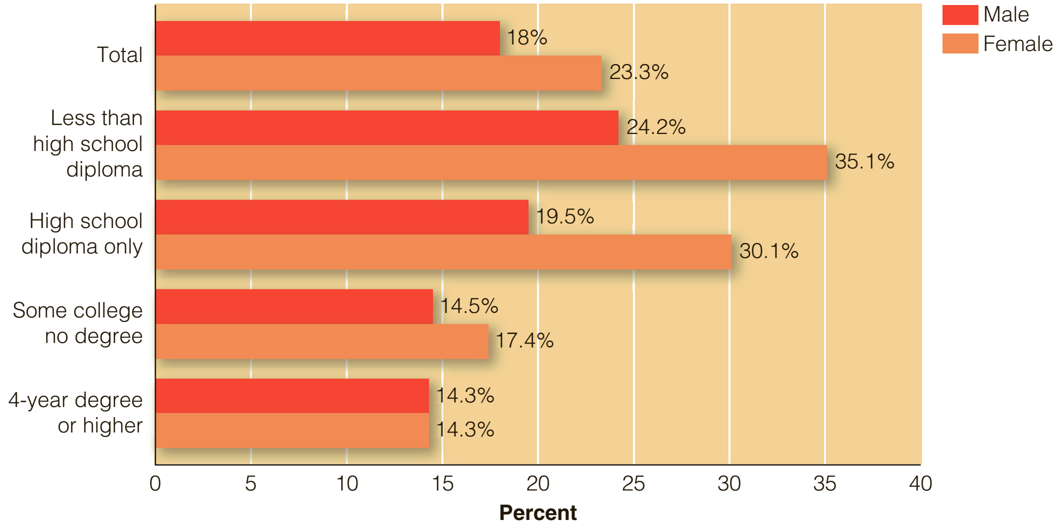


FIGURE 10.3 ▶ PERCENTAGE OF 18- TO 24-YEAR-OLDS IN POVERTY BY SEX AND EDUCATIONAL ATTAINMENT, 2009

Source: Aud, KewalRomani, & Frohlich, 2011.

In addition to poverty, one obstacle to financial self-sufficiency is the increasing burden of debt faced by many college students. Young people have mounting student loans as well as some credit card debt. Every year, about 12 million students borrow money to help cover the costs of higher education. For students who graduated from college in 2016, the average amount of student loan debt was $37,172 (Student Loan Hero.com, 2016). Repayment is a struggle for many, especially if they drop out of school before completing their degree, if they experience unemployment, or if they also accumulate credit card debt. A majority of students report that the amount of their student loan debt has impacted important life decisions like the choice of career, the ability to purchase a home, and saving for retirement. A substantial minority (over 20 percent) say that their student load debt has influenced a decision to delay marriage or to delay having children (ASA, 2015). Thus, although young people are encouraged to enroll in college, the rising costs and associated debt obligations slow their ability to achieve financial independence.

A sense of self-sufficiency goes beyond personal income. It is a subjective experience that is distinct from a person's living arrangement, student status, having a steady job, or being in a serious love relationship. A subjective sense of self-sufficiency is achieved gradually as young people face and meet important challenges of school, work, and family life and build confidence in their capacity to make good decisions. An appropriately structured, encouraging environment that scaffolds challenges so that students can experience increasing levels of competence fosters autonomy at the same time as it supports feelings of connection and belonging (Naude, Nel, van der Watt, & Tadi, 2016).

The process of achieving autonomy from parents opens the door to new considerations regarding gender identity, morality, and career aspirations. In each of these areas, a young person has the opportunity to *decenter*—to step back from the close socialization pressures of family and neighborhood—and construct his or her own point of view. After a period of role experimentation and **introspection**, some may choose to adopt the framework that was in place at the end of the high school years. Others may invent novel and nontraditional perspectives. The growth that takes place during the period of later adolescence in each of these areas reflects a willingness to evaluate multiple perspectives and to integrate personal commitments with societal expectations and resources.

FURTHER REFLECTION: Explain the idea of self-sufficiency. What does this term mean to you? What level of self-sufficiency would you expect someone in the age range 18–24 to have achieved? What are some of the obstacles to self-sufficiency?

Gender Identity

OBJECTIVE 2 Summarize the development of gender identity in later adolescence. Analyze how the components of gender-role identification that were relevant during the early-school-age period are revised and expanded.

In later adolescence, important revisions and elaborations of the child's earlier work on gender identification are taking place (see chapter 7). The formulation of **gender identity** refers to the acquisition of a set of beliefs, attitudes, and values about oneself as a man or a woman in many areas of social life, including intimate relations, family, work, community, and religion. The developmental task of forming one's gender identity reflects the need to integrate and synthesize three basic components of gender—its biological, psychological, and social meanings—into a view of oneself as a man or a woman entering the complex social world of adult life.

Four terms that are often used in discussing gender identity are masculinity, femininity, androgyny, and transgendered. **Masculinity** is typically associated with being instrumental, focusing on tasks and products, and *agentic* (i.e., having leadership abilities, being assertive, taking control); **femininity** is typically associated with being expressive, focusing on emotions and communication, and *communal* (i.e., valuing interpersonal and spiritual development, being tender, sympathetic, and concerned about the well-being of others). **Androgyny** refers to the capacity to express both masculine and feminine characteristics as the situation demands. **Transgendered** refers to people who do not identify with or present themselves as reflecting the **sex** they were born with and who move across or combine gender boundaries. The **Human Development and Diversity** box introduces the concept of the **third gender**, an idea that illustrates alternative pathways toward gender identity that exist in many cultures.

The Role of Culture

According to social role theory, *roles* are basic building blocks of social organizations. Every organization, including a family, workplace, community, and a culture, can be described by its roles. Individuals learn the roles of their social system throughout their lives. Through the socialization process, people internalize the expectations associated with many life roles and apply the socially shared norms and standards linked to these roles to their own behaviors. This process occurs with respect to gender-related roles as well as to kinship, age, occupation, and other socially constructed roles. For example, when a person becomes a parent, a man is called a *father* and a woman is called a *mother*. Both are parenting roles, but gender is identified.

All cultures construct gender-differentiated roles, and people expect one another to behave in certain ways because they are male or female. Perhaps more important, they form expectations of how men and women ought to act when they are together so that the distinctions between the genders are demarcated. These expectations are taught and learned, beginning early in life. Many important life events, such as the ritual of the wedding ceremony, highlight the distinctions between the male and female gender roles. For later adolescents, the gendered nature of the family is an especially important factor in shaping gender identity. Family experiences from the past provide the gender script with which they are most familiar. The family life they envision for themselves in the future creates many of the priorities that shape their current commitments and goals (Schlegel, 2009).

In the United States, many people argue that gender-based role distinctions are inappropriate, at least as a part of public life. They believe that men and women should be considered equal and treated identically in all public matters. But in many cultures, there are distinct, agreed-upon norms prescribing differences in how men and women are treated, which tasks they are expected to perform, and what status they hold in their family and community. Often, these norms establish specific power differences as part of the gender distinctions. Typically, men have more power than women, but this is not always the case.

Others argue that men and women should be considered equal, but that they should be treated in ways that take into account differences in their needs and capacities. For example current workplace guidelines recommend the creation of specific settings for nursing women.

> The Patient Protection and Affordable Care Act ("Affordable Care Act") amended section 7 of the Fair Labor Standards Act ("FLSA") to require employers to provide reasonable break time for an employee to express breast milk for her nursing child for one year after the child's birth each time such employee has need to express the milk. Employers are also required to provide a place, other than a bathroom, that is shielded from view and free from intrusion from coworkers and the public, which may be used by an employee to express breast milk. The break time requirement became effective when the Affordable Care Act was signed into law on March 23, 2010. (U.S. Department of Labor, 2016)

Cultures construct gender-differentiated roles. In the United States, the traditional attire of the bride and groom symbolize ideal images of feminine beauty and masculine respectability to which many young people aspire.

The experiences of immigrant youth to the United States illustrate the role of culture in shaping gender identity. Young people who immigrate with their families, sometimes referred to as the 1.5 generation, find themselves in the position of having to navigate contrasting norms and values regarding gender. Having been born and raised in a culture in which men are elevated to a higher status position and strict rules are applied in defining women's roles, they find themselves in an environment where new opportunities for status and roles are available. For example, it is not uncommon for immigrant girls to do better in school and to adapt more quickly to the educational opportunities in their new community than the boys. At the same time, immigrant boys are likely to be allowed more freedom to explore outside the home. Girls are held to a traditional standard for chastity and are expected to preserve traditional practices that they will pass on to the next generation. As a result, boys may experience conflict between reduced status in the eyes of teachers and school authorities in comparison to girls; and girls may experience resentment of their male siblings' freedom given their better performance and recognition in the school environment. Both males and females in the 1.5 generation have to construct new meaning of their gender roles in this transitional process (Stritikus & Nguyen, 2007).

HUMAN DEVELOPMENT AND DIVERSITY

Third Genders

Biologically, humans may be sexually dimorphic, but in many cultures there is evidence of alternatives that expand the dualistic perspective of male and female gender. Three examples of cultural traditions that have *third gender* categories are provided here as a way of illustrating the potential diversity of gender concepts. Many more examples can be found in anthropological writings (Nanda, 2001). Many cultures include alternatives to the traditional male and female categories that broaden the possibilities for pathways that individuals may follow as they crystallize their gender identity.

In Oman, a country in the Persian Gulf, *Xanith* is a term used to refer to biological males who function mostly as women (Nanda, 1998). In some Middle Eastern countries, this term is used as insulting slang for effeminate men. When asked, *Xanith* say they are women, but they are not entirely like women according to Omani standards. *Xanith* falls in between that of men and women. Under Islamic law, *Xanith* have all the rights of men and are allowed to worship with the men at the mosque, yet they are allowed to visit with women, eat with women, and walk arm in arm with women. The facial expressions, voice, laugh, movements, and swaying walk of the *Xanith* imitate those of women, but they wear clothing that is a mixture of men's and women's styles. *Xanith* are prohibited by law from wearing some women's clothing, including the mask and veil that all adult women must wear. A *Xanith* wears the ankle-length tunic typical for men, but it is belted tightly at the waist as a woman might do. In Oman both men and women cover their heads, but *Xanith* go bareheaded. Unlike women, *Xanith* move around freely outside their houses, though only during the day. Most importantly, *Xanith* are openly prostitutes, an activity that is not acknowledged for Omani woman. Thus, the *Xanith* demonstrate a third gender role in many aspects of their public self-presentation.

In India and Pakistan, the *Hijra* provide another example of a third gender. The *Hijra* have an ancient tradition, inspired in part by the Hindu deity, Shiva. Shiva is sometimes portrayed as half male, half female. The Sanskrit name for this form of the deity, *Ardhanārīśvara*, is best translated as "the lord who is half woman." This image is used to symbolize the idea that the sacred powers of the universe are both feminine and masculine (Pettis, 2011). Hindu thought allows for overlapping and even contradictory categories that support flexibility in gender roles. In general, *Hijra* are men who dress in women's clothing but do not try to hide their masculine features. When asked, they say they are not trying to be women but view themselves as both male and female. In some writings, the *Hijra* are described as eunuchs, and some do undergo surgeries to have their male genitalia removed. They appear at weddings, usually uninvited, to sing and dance and bring wishes for fertility. They expect to be paid for these performances, and usually they are. *Hijras* refer to themselves using feminine pronouns and expect others to do so. They typically live together in a commune arrangement of five or more chelas (disciples), supervised by a guru.

Among American Indian tribes, the two-spirit person is a native tradition that anthropologists have associated with some of the earliest discoveries of native artifacts. Before colonization and contact with European cultures, Native people believed in the existence of three genders: the male, the female, and the male-female gender, or what is now called the two-spirit person, a term derived from interpretations of Native languages used to describe people who displayed both male and female characteristics (Roscoe, 2000).

Ladi Kirn/Alamy Stock Photo

The *Hijra* of India are men who think of themselves as both male and female.

In the religious views of many Native people, humans are seen as minor relatives of goddesses and gods. When a human person is born, only one or the other spirit usually comes into substance, into life on Earth—the other half remains in the spirit world as a higher self. A woman may have her hidden male side, and a man may have his female side. Traditionally, the two-spirited person was one who had received a gift from the Creator, the privilege to house both male and female spirits in the body. Being given the gift of two spirits meant that this individual had the ability to see the world from two perspectives at the same time. This greater vision was a gift to be shared with all, and as such, two-spirited beings were revered as leaders, mediators, teachers, artists, seers, and spiritual guides. They were treated with the greatest respect and held important spiritual and ceremonial responsibilities (Williams, 1992).

These examples extend our thinking about gender. They illustrate cultural strategies for formalizing alternative understandings about gender. In some cultures and at certain times in history, people who embrace these alternatives have been persecuted or reviled, but in other cultures and at other times, people who claim a third gender identity have been recognized as having special powers or insights.

(Continued on next page)

Critical Thinking Questions

1. Express your reactions to the idea of a third gender. Explain how the concept of a third gender fits your own understanding of gender identity. How might it be possible to be neither male nor female? Or both male and female?
2. Explain why many indigenous people or cultures have conceived of a social identity for people who combine male and female qualities.
3. Whereas third gender individuals are respected and acknowledged as having their own social space in many non-Western cultures, individuals who exhibit these characteristics have been ostracized and stigmatized in many Western societies. Why is that?

Reevaluating Gender Constancy

Each of the components of gender identification discussed in chapter 7 undergoes some transformation as work on gender identity continues, including reevaluating gender constancy, reevaluating earlier gender role standards and learning new ones, and revising childhood gender identifications. What is more, a sexual dimension is added to gender identity.

Later adolescents can appreciate that the use of gender labels is a social convention and that, apart from the genital basis of this label, there are wide individual differences *within* gender groups in most traits and abilities. Moreover, information about genetic anomalies and medical technologies may lead later adolescents to realize that it is possible to have a conflict between one's genetic sex and one's gender identity.

Some young people, referred to as transgendered, develop a gender identity that is opposite to their biological sex. They feel certain of their gender, which is at odds with their genital features. In these cases, the possibility of sex-reassignment surgery combined with hormone treatments provides an alternative to the notion of gender constancy (Ettner, 2016). One study followed the adjustment of 20 adolescents who had experienced sex-reassignment surgery. In the 1 to 4 years following treatment, these young people were functioning well, and none of them expressed regrets about their decision (Smith, van Goozen, & Cohen-Kettenis, 2001). Later adolescents may realize that one's sex is not quite as fixed and constant as they may have believed. Furthermore, those who experience psychological conflict about their gender may learn that a new designation is not only possible but also desirable.

Reevaluating Earlier Gender-Role Standards and Learning New Ones

Gender-role expectations exist at the cultural, institutional, interpersonal, and individual levels. As later adolescents learn about these expectations, they must integrate and synthesize them with their assessments of their personal talents, temperament, needs, and goals. The content of gender-role standards—that is, the cultural and subcultural expectations concerning the appropriate behavior of male and female individuals—is different for later adolescents than for young children. For a 6- or 7-year-old boy, it may have been important to learn to be tough and not to cry or whimper, to stand up for himself, and not to hit girls. For a young man in later adolescence, the gender-role expectations may include holding a steady job, demonstrating sexual prowess, or being competitive. For a 6- or 7-year-old girl, the emphasis may have been on taking turns, not being too bossy, and staying clean. For a young woman in later adolescence, gender-role expectations may focus on being a caring, supportive friend; expressing maternal, nurturant behavior; or having an attractive figure and knowing how to dress well.

In later adolescence, young men and women begin to develop an analysis of what it takes to get ahead in their social world, whether success is defined as finding a mate, getting a good job, being a good parent, or being popular. They may learn to be more flexible in their interpersonal behavior, modifying their strategy to suit their goals. They discover that such traits as assertiveness, goal-directed behavior, competitiveness, being a good communication partner, personal disclosure, and negotiation are all required in social situations, and they learn to develop and apply them as required. In previous generations, some of the aforementioned traits were considered masculine and some feminine. Today, however, they are perceived as helpful to both men and women to be able to succeed in work and family life.

Gender-role standards may change from one generation to the next, so that parents who are socializing their children may have grown up with one set of gender-role expectations, but their children may enter later adolescence with a very different set of norms and expectations. For example, in a national survey of college freshmen, students were asked to respond to a number of statements about attitudes and values. One of those statements was, "Activities of married women are best confined to home and family." In 1970, 48 percent of freshmen agreed with that statement; 34 years later, in 2004, only 21 percent of freshmen agreed (*Chronicle of Higher Education*, 2005; U.S. Bureau of the Census, 1996). One could speculate that many of the parents who were college freshmen in the 1970s had more traditional gender-role attitudes than their children currently have. Societal changes related to education, employment, and views about marriage and childbearing combine to modify the outlook of both men and women on their appropriate and normative roles.

The U.S. culture is moving toward more flexible standards. It is normative for women, including married women with young children, to be in the labor market. The prevalence of dual-earner couples, combined with the increased educational attainment of women, has led to increases in career achievement and leadership roles for women in many fields. As a result, young women in early and later adolescence have numerous role models of women who are assertive, competitive, and achievement oriented. Young men in early and later adolescence have numerous role models of men who are effectively combining career and family-life roles, and who take pride in their ability to nurture and mentor their own children as well as younger workers. Many gender-stereotyped expectations about behaviors that are appropriate for men or women have been relaxed and replaced by a greater diversity of behavior that is considered acceptable for both men and women in our society.

The greatest impact of this revision of tightly scripted gender roles is on the later adolescent population as they formulate their gender identities. There are more options, choices, and goals, and fewer obstacles to expressing personal preferences. Many social influences including family, friends, romantic partners, media, university culture, and religious and political figures contribute content to the young person's conception of gender norms. Later adolescents incorporate this diversity of views about gender-role standards and expectations into their self-concept, and these internalized standards guide their behavior. Yet, later adolescents are not simply passive recipients of these influences. They transform this information into conceptions of a future self; and as a generation they often bring about social change, endorsing new visions of how gender is expressed through song, fashion, media, creative arts, and in day to day interactions (Bussey, 2011). Research with college-age students demonstrates how gender-role standards serve a regulatory function. Students report increases in self-esteem and positive emotions when they behave in ways that conform to their own gender-role standards, and more distress when they behave in ways that conflict with these standards (Witt & Wood, 2010).

Even as gender-role standards are becoming more flexible in the United States, certain ethnic groups face new conflicts between adhering to traditional cultural expectations and embracing gender roles that are less scripted. For example, Mexican American women experience a strong cultural emphasis on the role of women as mothers who are nurturing, virtuous, and devoted to their husbands and children. This gender-role standard places pressure on them to restrict their occupational aspirations and to remain close to their family of origin, particularly when it comes to thinking about going to college or planning a career (Wright, Mindel, Tran, & Habenstein, 2012). In later adolescence, however, these young women must review these expectations, weighing the benefits they have had from this kind of close, attentive mothering with their own changing desire for higher levels of educational and occupational attainment. For some young women, this conflict results in psychological distress as they struggle to balance their commitments to home and family with their desires for challenging and rewarding careers. As economic demands and educational opportunities have expanded, Mexican American women have found ways to satisfy their community's traditional expectations while still claiming some space for their own personal goals (Denner & Dunbar, 2004).

Revising Childhood Identifications

The component of parental identification that contributes to gender identity is also reviewed and revised in later adolescence. During this time, young people begin to encounter a wide range of possible targets for identification. In the college environment, students meet teachers, residence hall counselors, and older students whose views and values may differ widely from those of their parents. Outside the college environment, workers meet supervisors, other workers, and social companions whose views and values may differ widely from those of their parents. Later adolescents may admire public figures, such as religious leaders, political leaders, artists, or scholars, whose work and ideas are especially inspiring. In the process, later adolescents revisit the content of their parental identifications. They analyze those beliefs, attitudes, and values that they may have swallowed whole as children, evaluating which of them are still relevant to their own personal vision of themselves functioning as a man or a woman in their current situation. They try to determine whether the lessons they learned as children about how husbands and wives, fathers and mothers, and men and women treat each other and think about each other remain applicable.

The opening case provides examples of how a young man may revise his childhood identifications. In his youth, the boy was always trying to meet his mother's emotional needs which also created a certain degree of stress. Now, in his later adolescence, he sees how this pattern of behavior tied to his identification with his mother led him to be preoccupied with worries about pleasing others. Coming to college and being away from his family allowed him to review and revise his childhood identifications. Hopefully, this insight will allow him to behave more flexibly in his own relationships in the future.

Adding a Sexual Dimension to Gender Identity

In addition to revising parental identifications, later adolescents add a sexual dimension to their gender identity. Biological changes of puberty, including changes in reproductive capacities, secondary sex characteristics, body shape, height, weight, and strength, must be incorporated into one's gender identity.

Satisfaction with one's physical appearance provides an important basis for approaching social relations with a positive, optimistic outlook. Furthermore, it may influence one's attractiveness or initial desirability as a sexual partner. In contrast, dissatisfaction with one's physical appearance as integrated into the self-concept may interfere with the formation of positive social relationships, causing the person to approach interpersonal contacts with self-consciousness and a pessimistic expectation that he will be rejected.

Maturation of the hormonal system, which influences emotional arousal as well as sexual urges, contributes to the development of one's gender identity. The hormonal changes of puberty bring new sexual impulses as well as the capacity for reproduction. Hormonal changes may also contribute to changes in the basis of relationships, increasing attention to new emotions, such as jealousy, love, depression over loss of love, sexual arousal, and passion. Individual differences in hormone levels are linked to gender-role characteristics.

The general term for male sex hormones is **androgens**, the most prevalent of which is *testosterone*. Androgens, especially testosterone, are associated with sexual arousal, interest, and behavior. This relationship is observed in both men and women. For men, higher levels of androgens are associated with both increased sexual motivation and increased involvement in sexual activity. For women, higher levels of androgens are associated with increased sexual motivation, but **estrogens** appear to be implicated in their willingness to engage in sexual activity. This may be a result of the fact that estrogens contribute to the maturation of primary and secondary sex characteristics that make women more sexually attractive. In general, hormone levels are not as good a predictor of sexual activity for women as are the social contexts of family and peer group and the woman's own internalized standards about sexual behavior (Crooks & Bauer, 2014).

There is growing concern about the sexual and reproductive health of young people in their early 20s (Boonstra, 2009). Later adolescents are more likely than those in their late 20s and 30s to be involved in multiple sexual relationships, with little intention of permanency or desire for having children. Norms within some college environments appear to be particularly supportive to casual relationships.

> Lydia just simply stated "I think it's hard to not be sexually active in college" because of an existing "culture of sex" on college campuses. She elaborated by stating:
>
> Like a lot of people always talk about freshman and sophomore year, they're very promiscuous ... I don't know if I'd say that it's considered a good thing or a bad thing. But it's certainly not considered an unexpected thing, to sort of have casual sex ... I think, there, that definitely is a culture thing like you should go out and you know it's cool if you can hook-up with someone on the weekend. (Fantasia, 2009, pp. 82–83)

College women describe a complex set of messages from friends about sex and romantic relationships. Despite the impression implied in the preceding quotation that campuses are characterized by a "hook-up" culture, friends actually provide a diverse and somewhat contradictory set of messages about how to navigate the landscape of sexuality. In one study, over 400 undergraduate women reported about the messages they received from their male and female friends about sex and romantic relationships. There was no consensus about advice. The messages were neither wholly permissive (do what you want) nor wholly conservative (wait until marriage). Few women received advice that focused on sexual desire (e.g. just do what you want and enjoy yourself). Many women described complex advice that combined encouragement within boundaries, especially from female friends (e.g. "My female friends have always said to enjoy yourself while in college but don't go overboard with sexual partners."). Most women reported a pretty traditional message—friends tell them to evaluate the context of the relationship before deciding to have sex. In addition, friends, both males and females warned of the double standard (e.g. "Men can sleep around and it's a good thing but when women sleep around it's *skanky.*"). In addition, friends advised women to be *safe, smart, and careful* without giving specific advice about sexual health. In general, more messages from male friends were sex-positive messages; more messages from female friends emphasized reputational implications as well as emotional and health consequences of being too open or too casual about sexual behaviors (Trinh, 2016).

College students are well aware of the risks of unplanned pregnancy. Nonetheless, in 2014 there were 579,760 births to unmarried women ages 20 to 24, and approximately 200,000 abortions (Hamilton et al., 2015; Pazol, Creanga, & Jamieson, 2015). Later adolescent males and females are at especially high risk for sexually transmitted infections (STIs). In 2014, 20- to 24-year-old females and males had the highest rates of chlamydia, gonorrhea, and syphilis of any age groups, and there were 7,114 newly diagnosed cases of HIV in this age group (CDC, 2015f, 2015g).

As a group, later adolescents are more mobile, less connected to a specific community, and therefore less linked to health care services that might meet their needs. With the executive function still maturing, they are greater risk takers and more likely to have multiple, temporary sex partners than somewhat older adults. They are less likely to check with their intimate partners about their sexual health.

Sexual Orientation. During later adolescence, young people are engaged in an active process of integrating their sexual fantasies, experiences of sexual arousal, and understanding about sexual behavior into a sexual identity. Research on gay, lesbian, and bisexual (GLB) sexual orientation suggests the following sequence of milestones in the formation of sexual identity: initial attraction to a member of the same sex; identification of oneself as having a gay, lesbian, or bisexual orientation; first sexual experience; and first disclosure to others of one's sexual orientation (Calzo, Antonucci, Mays, & Cochran, 2011). Research with a large national sample found that there are different patterns to timing for the unfolding of this sequence, but that the sequence of milestones is relatively consistent no matter at what age a person begins this process. The most common pattern, for about 75 percent of the sample, begins in early adolescence; the next most common pattern begins in later adolescence; and the least common pattern begins in middle adulthood. Among those who begin self-identification early, about one third begin to have sexual attractions at around age 8 and final disclosure occurs by age 18. More commonly, initial attraction begins at around age 14, and disclosure takes place in the early 20s. Females report a somewhat older age at first attraction and first sexual experience, but an earlier age at disclosure to others than do males.

Later adolescents who may have struggled with acknowledging or accepting their sexual orientation during the high school period are likely to resolve these inner conflicts and disclose their sexual orientation to others. This process is fostered by support from at least one close person and by increasing involvement in the gay community. Although disclosure has its risks, failure to disclose or trying to continue to pass as heterosexual is typically associated with strong feelings of isolation and self-repudiation (Troiden, 1993).

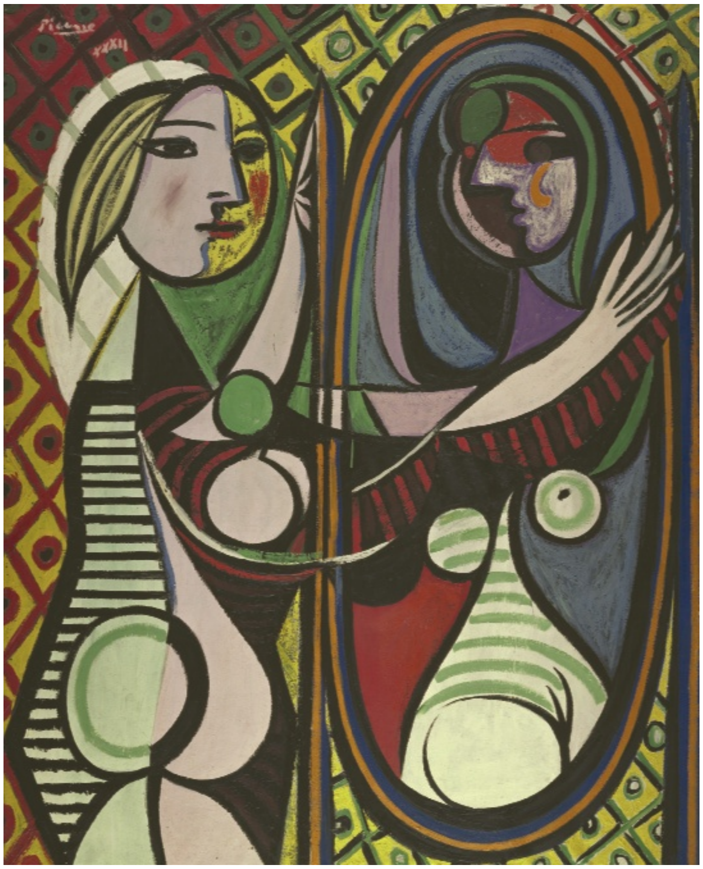
Research on sexual identity development finds patterns of both consistency and change. One study followed a group of males and females recruited from a variety of GLB community and campus organizations over a 2-year period. About 40 percent self-identified as gay or lesbian, 40 percent self-identified as gay/lesbian and bisexual, and 20 percent self-identified as bisexual. Over the 2-year period, those who initially self-identified as gay or lesbian were most likely to remain in this group whereas those who self-identified as gay/lesbian and bisexual were most likely to identify as gay or lesbian. Among those who initially self-identified as bisexual, the majority continued to endorse this orientation, but about one third identified as gay or lesbian. In general, women were more consistent in their sexual identity over the period than were men. For both males and females, those who consistently self-identified as gay or lesbian rather than bisexual were also more certain and comfortable with their sexual identity, had more positive attitudes about homosexuality, and were more comfortable about allowing others to know about their sexual orientation. As later adolescents crystallize an alternative sexual identity, it appears that a less ambiguous status as either gay or lesbian is easier to navigate and is accompanied by less personal and social uncertainty than a bisexual orientation (Rosario, Schrimshaw, Hunter, & Braun, 2006).

Integrating One's Gender Identity

Young men and women formulate their gender identities as they encounter diverse and sometimes competing social messages, role relationships, sexual motives and activities, and dyadic interactions. These gender identities are situated in interpersonal, institutional, and cultural contexts. One of the salient factors contributing to the emergence of gender identity is gender-role preference. This preference is based on an assessment of two factors: how well one can meet the cultural and social expectations associated with one's gender, and how positively one views the status associated with it. The idea of gender typicality was introduced in chapter 7. As the norms for gender-related expectations shift, later adolescents may revise their view of whether their own physical appearance, traits, preferences, and talents are typical for their gender. Picasso illustrates the complexity of this process in his painting of the girl before the mirror. In this image, we observe the construction of an inner and an outer self, a reflected self, a physical self, and a desire to embrace all elements of the self.

Later adolescents' views about their gender typicality may become more differentiated. For example, Laura realizes that she has personal ambitions for career success and the accumulation of wealth that are not typical of other women in her friendship group or her family. Yet, she still sees herself as fitting in with her female friends and spending time in shared activities, including shopping for new clothes, volunteering at the senior center, and playing tennis. Her friends tease her about wanting to make her first million dollars by the age of 25, but they admire her for it as well. As her personal identity becomes clearer, she can accept that she is similar to other women in many respects and different from them in others.

Later adolescents can view themselves as personally and socially typical of their gender and still not be satisfied with their gender if the culture or context assigns a low status to their gender. If later adolescents become aware that their gender prevents them from having access to resources, influence, and decision-making authority, they are likely to experience a decline in their gender-role preference. This could happen to men as well as women, depending on the paths they choose to pursue and the gender biases they encounter. For example, in general, we tend to think of career aspirations as being stifled for women as a result of attitudes on the part of men who think that women are not suited to certain types of work. However, the reverse situation may apply to men who are interested in fields such as early childhood education or nursing.



SuperStock

The crystallization of gender identity requires the integration of one's sexuality, including physical appearance, primary and secondary sex characteristics, sexual drives, and fantasies. One's sexual identity is as much a mental representation as a physical reality.

If later adolescents perceive that, apart from real differences in ability, one gender group is treated with greater respect, given more opportunities, and responded to with more attention or greater rewards, then their gender-role preferences are likely to be recalibrated. During the high school years, adolescent girls are likely to encounter stereotyped expectations that restrict their behavior, judge their appearance, or label them as *sluts*. Sometimes, these stereotypes intersect with race and social class, especially as they encounter negative expectations from teachers or suspiciousness from shopkeepers (Abrams, 2003). Strict cultural norms regarding femininity, especially about body type and sexual behavior, can result in negative affect and alienation. Although some young women give in to these pressures, others resist, refusing to give up their voice or their autonomy in the face of adult judgments:

> Well, a lot of adults—they look at me kinda like, "ooh, she's like really crazy looking," or something like that. And my mom always says "oh, people are gonna think you're a bad girl." And I'm like "Whatever. I don't care." (Abrams, 2003, p. 71)

College students do not see much of this type of gender discrimination or preference. They tend to view the college environment as providing many opportunities and equal access to resources for both male and female students. In fact, women outnumber men as college students and exceed men in the percentage of students earning master's degrees in the United States. Women are the majority of students in all but a few majors including engineering, mathematics, chemistry, and physics (Diprete & Buchmann, 2013). Moreover, both male and female students feel equally oppressed by the stressors of college life and the uncertainties associated with the decisions they are trying to make. Typically, it is not until they enter the world of adult employment that they begin to experience the power differential that continues to operate to the benefit of White men in U.S. society (Heilman, 2001).

Later adolescents who enter the world of work at the end of high school are confronted by the power differential immediately and may experience intimidation that forces them to accept it. For example, a woman who makes $2 per hour less than a male counterpart may be afraid to say anything because she needs the job. She will have to integrate the reality of what she experiences into the formulation of her gender identity. One strategy is to accept that this is the way things should be according to gender-role norms—that women should defer to men and their contributions should be treated as less worthwhile. Another strategy may be to look for a different kind of work in a setting where women and men are paid equally.

The college population tends to set social trends by according more variety and less rigidity to sex-linked role expectations. Most studies find that during the college years, students become more flexible in their gender-role attitudes and more egalitarian in their views about how men and women ought to function in school, work, family, and community life. On the other hand, the non-college population tends to set employment trends by breaking down barriers in many male-dominated areas of work, such as construction, trucking, and public safety. Individuals can shape and strengthen the nature of their gender identity by spending time with other people who support their views and values about how men and women ought to behave toward one another and what life paths are most desirable for them.

FURTHER REFLECTION: *Hypothesize about how experiences in college might influence gender identity. How might men and women differ in the ways they are affected by their experiences in college? How does one's gender identity influence a person's sexual behavior? Examine possible connections between academic performance, school engagement, the sense of belonging, and the sense of gender satisfaction.*

Internalized Morality

OBJECTIVE 3 Investigate the maturation of morality in later adolescence, with special focus on the role of new cognitive capacities that influence moral judgments and the various value orientations that underlie moral reasoning.

In early school age, morality consists primarily of internalizing parental standards and values, recognizing the difference between right and wrong, and learning to control one's behavior in anticipation of its moral consequences. As young people achieve new levels of autonomy from their parents and encounter new situations, they discover that some of the moral principles they learned as 6- or 7-year-olds neither apply to the new situation nor provide much of a rationale for why they should behave one way and not another. Later adolescents explore the distinction between *social conventions* and *moral issues*. Behaviors that may have been viewed as moral issues during childhood may be reevaluated as social conventions. The domain of personal preference or personal choice expands, resulting in a reorganization of one's moral thinking.

Within the overall process of formulating a personal identity, later adolescents devise a more mature **internalized morality**. They begin to see themselves as moral beings whose actions have implications for the well-being of others. They make moral commitments and judge their behavior and the behavior of others according to new moral standards (Damon, 1996, 2000). The three elements of morality—judgment, caring, and action—come together in an increasingly complex political, social, and interpersonal environment (Nucci & Turiel, 2009). Morality may be expressed in a variety of behaviors, including acts of consideration and kindness; resistance to temptation; opposition to unfair laws, rules, or practices; activism and civic engagement; and contributions of time, money, or other resources to enhance the well-being of others. The emerging moral synthesis suggests an active approach to moral situations in which young people evaluate the situation, consider salient values, and reflect on the consequences of possible actions as they decide on their response (Turiel, 2015a). The following sections examine Kohlberg's analysis regarding advances in moral reasoning, experiences that promote moral reasoning, and the expansion of research on moral development, which includes prosocial behavior and the ethics of care.

New Cognitive Capacities

Later adolescents bring new cognitive capacities to the arena of moral decision making. Research in cognitive neuroscience has emphasized the role of "hot" cognition, fueled by the limbic system, as contributing to risky behaviors and a focus on rewards. Nonetheless, the maturing executive functions cannot be overlooked. Later adolescents approach moral conflicts with new capacities for weighing alternatives and considering possible outcomes (Turiel, 2010). They are able to use abstract reasoning to consider the logical consequences of their actions, both for themselves and for others. They can project alternative paths in a probabilistic future and consider the multiple perspectives that are possible in a moral situation.

Most societies are structured around certain group inequalities in power, resources, and freedoms. Later adolescents can consider how resistance against certain laws, rules, or normative practices by a subordinated group, such as women, ethnic minorities, or religious or sexual minorities, can be viewed as morally justified by the less powerful group and morally wrong by the dominant group (Turiel, 2006). They are increasingly aware of the rights and needs of others, and to consider how an action may satisfy their own needs but harm others. They can reflect about how principles of social responsibility, human rights, and justice can be preserved in a moral decision.

Stages of Moral Reasoning

Building on Piaget's theory of cognitive development, Kohlberg (1964, 1969; Colby & Kohlberg, 1987) suggested that a qualitative change in a person's ability to reason about moral issues is expected from early school age to later adolescence. With age and exposure to moral conflicts, **moral reasoning** advances in much the same way that other domains of logical reasoning mature, from an early reliance on direct perceptions and immediate consequences to more complex, abstract, and relativistic judgments. Kohlberg's theory includes three levels of moral reasoning divided into six substages (see chapter 7, Table 7.1).

At Stage I, the **preconventional level**, from about age 4 to 10, children judge an action as morally justifiable based on the immediate consequences of the behavior and the approval of powerful authority figures. Stage II, the **conventional level**, from about age 10 to 18, reflects a concern about the maintenance of the existing rules and laws and a respect for legitimate authority. Stage III, the **postconventional level** of moral reasoning, from about age 18 into adulthood, brings an awareness of social, cultural, and political processes that result in the formulation of rules and laws. Morality is understood as a system of rules that are agreed upon in order to preserve human rights and social order. These rules have been created in cultural and historical contexts and can be altered as the norms of the community change. Beyond this appreciation for the **cultural relativism** of moral principles, a commitment emerges to overarching universal moral principles, including greater concern for the value of human life, human dignity, and justice for all members of society. The proportion of people who reach this final level of moral reasoning is small but increases during early and middle adulthood.

Longitudinal data provide evidence of the sequential nature of the stages during childhood and adolescence (Colby & Kohlberg, 1987; Colby, Kohlberg, Gibbs, & Lieberman, 1983; Nisan & Kohlberg, 1982; Snarey, Reimer, & Kohlberg, 1985). The sequence of stages proposed by Kohlberg is noted in a variety of countries outside the United States including Israel, Turkey, the Bahamas, Honduras, Mexico, India, Kenya, Nigeria, and Taiwan. Participants in these studies used forms of reasoning similar to those used by U.S. samples. The adults and adolescents in every culture used levels of reasoning that were higher than those used by the children (Colby & Kohlberg, 1987; Dawson, 2002; Nisan & Kohlberg, 1982; Rest, 1983; Snarey et al., 1985). The stages reflect qualitatively distinct ways of reasoning about moral dilemmas that are supported by increasingly complex cognitive capacities (Dawson, 2003).

Experiences That Promote Moral Reasoning

Later adolescents must formulate an integrated value system with which to guide their behavior, particularly in the face of strong pressures to violate their moral beliefs. Young people encounter situations that require moral evaluation, judgment, and decisions about action. Dilemmas about using illegal drugs, plagiarizing, or violating religious traditions and practices may confront a young person who is away from home for the first time. In these situations, the young person has the opportunity to envision the self as a moral actor and take a course of action most congruent with other facets of his personal identity.

Although the *sequence* of moral stages appears to be well established, the level of moral reasoning that an individual actually attains depends on the kinds of moral challenges and situations encountered. For college students, like the one in the following example, the academic curriculum itself often creates a degree of cognitive disequilibrium that promotes a revision in moral reasoning.

> I was taking a theology class as a freshman in college and was presented with "bold" alternatives to understand and interpret the creation story—primarily to understand it as a myth. My life up to that point was characterized by asking many questions but arriving at few answers. To those in my fundamentalist background, those questions were annoyances but not insurmountable problems. In my shift to some answers to those questions, I moved away from fundamentalism to a more broadly based and responsible manner of critical thinking. The professor was very bright and responsible, yet in a sophisticated way he was somewhat irreverent. I was troubled by the dilemmas that this posed for me in terms of my belief structures, but something about the information and the self-assurance of the professor encouraged me to embrace this new way of thinking. (Chickering & Reisser, 1993, p. 240)

Through participation in thought-provoking discussions or challenging life experiences, moral reasoning can advance to the next higher level. Social and educational experiences promote moral reasoning when they draw on existing constructs, but they also challenge those constructs by making their inadequacies clear. Many young people participate in community service, such as volunteering at a soup kitchen or tutoring younger children in reading or math (Seider, 2007). These experiences can stimulate discussions about differing points of view and a more complex analysis of the many interdependent factors that contribute to the social order. Many communities have established youth development programs that involve adolescents in community service. As a result, a growing number of young people gain new insights into moral situations (Nasir & Kirshner, 2003; Yates & Youniss, 1996). In a study of 12,000 college students, Sax and Astin (1997) found that participation in community service during college had long-term consequences for adult involvement in volunteering, community activism, and helping others. A student at UCLA described her experiences:

> As a volunteer for the UCLA Medical Center, my conversations with chronically ill patients made me realize the profound emotional drain caused by long-term hospitalization. With each visit, I wished there was something more than my compassion that I could use to bring vibrancy and warmth back into these patients' lives. In 2004, I used my background playing the piano and flute to create the volunteer organization, Music to Heal, through which I arrange for student musicians to bring music into the lives of hospital patients. (Mahanian, 2008, p. 27)

Exposure to a diversity of information, relationships, and worldviews stimulates moral reasoning. The change from conventional to postconventional morality that begins during adolescence involves a rethinking of traditional moral principles. During this period, there may be a loosening of ties to the family of origin and an increase in encounters with an expanding network of friends, students, and coworkers. Interactions with diverse reference groups stimulates an increasing recognition of the subcultural relativity of one's moral code. There may also be a degree of conflict over which moral values have personal meaning.

A Maturing Moral Identity

Kohlberg's view of moral development focuses on reasoning or moral knowledge, not on the emotional or behavioral aspects of morality. One criticism of the theory is that studies do not find a consistent relationship between a person's level of moral reasoning and that person's willingness to behave in a morally caring way. To address this concern, researchers have taken the approach of identifying **moral exemplars**—people who have dedicated themselves to improving the lives of others—and comparing them to others who are not especially exemplary (Hart & Fegley, 1995). The moral exemplars are not more complex or advanced in their *reasoning* than the comparison group. What the exemplars demonstrate is a **moral identity**—a sense in which they define themselves in moral terms and evaluate their behavior against moral standards. Moral identity reflects an integration of parental socialization about caring for others, an appreciation for the cultural and social contexts of moral actions, and experiences that have required moral action (Colby & Damon, 1999; Reimer, 2003). The formation of a moral identity implies a desire for a sense of congruence between one's values and one's actions. Once a moral identity is established, behaving in an immoral or indifferent manner to the plight of others produces strong negative emotions of shame and guilt (Blasi, 2013; Tangney, Stuewig, & Mashek, 2007).

A second criticism of Kohlberg's approach to understanding moral development is that his theory is based on a specific method that emphasizes **prohibitive moral judgments**, in which a person is asked to reach a decision about violating a law or breaking a promise in order to achieve some other goal. A typical example is the case of Heinz, a man who is faced with the dilemma of having to steal a drug from a pharmacist if he is to save his wife's life. These dilemmas place justice—usually framed in terms of the legitimate needs or rights of the individual—in conflict with rules, laws, authority figures, and the obligations associated with adhering to these rules or laws.

Not all moral dilemmas are of this type. Some moral judgments involve a conflict between doing something helpful for someone else and meeting one's own needs. An example would be stopping to help a person whose car has stalled on the highway at the risk of being late for a very important job interview. Some moral judgments involve doing something helpful or caring despite having to violate an existing law or social norm. These dilemmas are described as **prosocial moral judgments** (Turiel, 2015b). The prosocial aspect of morality includes a concern for the welfare and rights of others and a willingness to act in order to benefit or enhance the lives of others. Just as society depends on people adhering to rules and laws in order to preserve order, it also depends on a commitment to caring. People seem to be able to think more flexibly about a prosocial moral dilemma than about a prohibitive one. Moral decisions that draw on empathy and concern for the well-being of another person tend to evoke a higher level of moral reasoning than those that would require breaking a law (Eisenberg & Fabes, 1998; Eisenberg & Strayer, 1987).

Expanding on the theme of prosocial morality, Carol Gilligan (1977, 1982 /1993, 1988) challenged Kohlberg's perspective. She argued that his description of the developmental course of reasoning about moral dilemmas is incomplete because it is based largely on the reasoning of male respondents about hypothetical rather than real-life situations. She claimed that men and women have distinct orientations toward moral dilemmas. According to Gilligan, women approach moral decisions with greater sensitivity to the context of the problem and a strong sense of **caring** focusing on one's responsibility for others and feelings of connection to them. Gilligan asserted that men, in contrast, emphasize abstract principles, rules, and laws, and the conflicts between the rights of the parties involved in the conflict. A woman, for example, might ask which outcome of a moral dilemma would result in the least harm for all concerned, whereas a man might ask whether one person has the right to infringe on the rights of others (Friedman, Robinson, & Friedman, 1987). These differences, according to Gilligan, are the product of different socialization patterns and result in different orientations to values, family life, and the basis of self-worth.

The research is inconclusive regarding whether men and women differ in their use of what have come to be called the **justice orientation** and the **caring orientation**. It appears that experiential and situational issues, as well as concerns about interpersonal obligations and caring, are more dominant in open-ended responses from both men and women than are issues of justice and individual rights. However, with age, both men and women add more autonomous, justice-oriented reasoning to their repertoire (Colby & Damon, 1994; Galotti, 1989; Galotti, Kozberg, & Farmer, 1991; Walker, de Vries, & Trevethan, 1987). The tendency of men and women to approach a moral dilemma using a justice-based or a care-based form of reasoning often depends on the social distance between the self and the other person involved. Regardless of gender, a caring orientation is more likely when the other person is viewed as a close friend or a member of one's relevant social group; a justice orientation is more likely when the other person is viewed as a member of an out-group, a stranger, or when the nature of the relationship to the other person is not specified (Ryan, David, & Reynolds, 2004).

In studies of prosocial behavior and empathic response to others, gender differences are commonly observed. Women report more caring behaviors, are rated as being more kind and considerate than men, emphasize the importance of helping others as a value, and exhibit more personal distress when faced with the distress of others (Eisenberg, Morris, McDaniel, & Spinrad, 2009). In many cultures, family socialization practices emphasize the importance of prosocial behavior and social responsibility for female children. As a result of this focus, perhaps women are more likely than men to integrate a prosocial orientation into their gender identity (Froming, Nasby, & McManus, 1998).

The process of achieving a moral identity is made more difficult in a pluralistic society, where one's moral perspective may be at odds with the perspective of others. Individuals emerge into later adolescence from different cultural and community groups whose moral frameworks derive from distinct configurations of basic principles. To some extent, these differences reflect divergent emphases on how moral agents and actions are understood. One approach to this idea of moral pluralism has been to identify three moral ethics: the Ethic of Autonomy, the Ethic of Community, and the Ethic of Divinity (Jensen, 2008, 2015). The Ethic of Autonomy refers to a focus on the moral agent as an individual and emphasizes principles such as the individual's well-being, welfare, and fairness to others. The Ethic of Community refers to a focus on the moral agent as a member of a social group and emphasizes principles of duty, the interests and well-being of the group, and the avoidance of social sanctions that would harm the group's reputation. The Ethic of Divinity refers to the person as an agent of a spiritual force and emphasizes religious or scriptural authority and spiritual duty. Whereas the Ethic of Autonomy is prevalent throughout childhood and into adolescence and adulthood, one sees new evidence of an emerging application of the Ethic of Community and the Ethic of Divinity in later adolescence and adulthood. What is more, the Ethic of Divinity may be applied more broadly by some religious subgroups whereas the Ethic of Community may be applied more broadly by others (Jensen & McKenzie, 2016). This can lead to different views about how a specific issue, such as capital punishment, or divorce or infidelity between marriage partners, is understood and judged.

Certain groups are consistently wronged by deeply ingrained inequalities in the social structure. Acts of resistance or subversion by groups in positions of less power may be labeled as immoral by those in higher positions and as heroic by those in the disenfranchised groups (Turiel, 2003). In later adolescence, young people begin to appreciate the moral ambiguities of their communities and may take action to express their commitments to justice and care through individual or group efforts. The concept of **civic purpose** captures this commitment to "contribute to the world beyond the self in the sociopolitical domain for example through community leadership, political activity, or participation in volunteer organizations" (Malin, Ballard, & Damon, 2015, p. 104).

Whereas some young people have been characterized in the media as self-indulgent and socially indifferent, others are intensely engaged in actions fueled by the passion of indignation about social injustice or commitments to service. The current cohort of college freshmen express a variety of attitudes and behaviors that suggest enthusiasm for civic engagement. About 75 percent say that helping others in difficulty is an important personal objective. Over 40 percent say that they want to influence social values, promote racial understanding, and believe that keeping up to date on political affairs is very important. Although a small minority (8.5 percent) say that there is a good chance they will participate in a student protest or demonstration while in college, this is the highest percentage reported since the survey first began asking the question in 1967 (Eagan et al., 2015). Evidence of this expression of moral identity through civic engagement can be seen in recent campus protests. These events were reported in *The Atlantic* (Wong, 2015):

- There was the confederate-flag fiasco at Bryn Mawr, which resulted in a mass demonstration by hundreds of students who, all dressed in black, called for an end to racism on the Pennsylvania campus.
- A week later, more than 350 students staged a similar protest further north, at New York's Colgate University. That one—dubbed #CanYouHearUsNow—likewise aimed to end bigotry among students and faculty; it was in part prompted by a series of racist Yik Yak posts.
- Students at the University of Chicago hosted a #LiabilityoftheMind social-media campaign last November to raise awareness about institutional intolerance.
- Roughly 600 Tufts students lay down in the middle of traffic in December for four and a half hours—the amount of time Michael Brown's body was left in the street after being shot. Students at numerous other colleges did the same.
- Early last fall, Emma Sulkowicz, then a student at Columbia, pledged to carry a mattress on campus daily to protest the school's refusal to expel her alleged rapist. Soon, hundreds of her classmates joined her, as did those at 130 other college campuses nationwide, according to reports. Anti-rape demonstrations became a frequent occurrence as colleges across the country came under scrutiny for their handling of campus sexual-assault cases. There were walkouts and sit-ins, canceled speeches and banner campaigns. Last May, the U.S. Department of Education reported that it was investigating 55 colleges and universities for possible violations of Title IX. As of this January, the number had gone up to 94.

Students who had a community service experience in high school were more likely to expect to continue this type of commitment during college. Volunteering has been found to be strongly associated with two aspects of moral commitment: social agency, or a personal goal of being politically and socially active in the community, and valuing and respecting other groups' points of view. This large and growing group of college students provides a very hopeful indication about the willingness of the new generation of young people for combining a caring and a justice orientation in order to make contributions to their communities.

EDUCATION IN AMERICA: DON'T BANK ON IT!
Education is not a marketable Product.

David Grossman/Alamy Stock Photo

College students, graduates and activists protest the ways banks finance college education which increases capitalist profits while creating student debt.

FURTHER REFLECTION: *Describe an experience in later adolescence that has had an impact on your moral values or your approach to moral judgments. What should colleges and universities strive to achieve in the domain of fostering moral maturity among students? What messages does your college or university convey about moral and ethical behavior?*

Career Choice

OBJECTIVE 4 Trace the process of career choice, with attention to education and gender-role socialization as two major influential factors.

The choice of occupation sets the tone for one's early adult lifestyle. The world of work determines daily routines, including the time one wakes up, daily activities, expenditures of physical and mental energy, and conditions for both immediate and long-term rewards. Because one's occupation has implications for income and earning potential, **career choice** will influence one's personal financial resources and opportunities. Occupation confers social status and provides varying opportunities for advancement. Finally, it represents a direct or indirect expression of one's value system. In subsequent chapters, we will discuss socialization in the work setting and the management of a career. Here, we focus on the process of career choice and its relationship to development during later adolescence.

Work Experiences in Early Adolescence

Later adolescence is not the first time young people encounter the world of work. Many early adolescents hold part-time jobs while they attend high school. In 2015, 34 percent of 16- to 19-year-olds were in the labor force. Of those in the labor force, 17 percent were unemployed—meaning that they were recently fired or had been unsuccessful in looking for work during the preceding 4 weeks (Bureau of Labor Statistics 2016a). These data suggest that it is currently more difficult for young people to enter or remain in the labor market than was the case 30 years ago when roughly 60 percent of teenage boys and slightly over 50 percent of teenage girls were employed.

There is some controversy about the benefits of working during high school and whether these work experiences make a positive contribution to the occupational component of identity development. A number of investigations have found that high school students who work long hours in stressful jobs are more likely to evidence increased cigarette smoking, marijuana and alcohol use, receive lower grades, earn fewer course credits, and are more likely to drop out of high school (Entwisle, Alexander, & Olson, 2005b; Marsh & Kleitman, 2005). Students who work long hours have less time for school activities, spending time with friends, or developing other areas of interest. The kinds of work opportunities that are available to adolescents are usually minimally skilled jobs with high turnover, low pay, little decision-making responsibility, and little stimulation of skill development. These kinds of jobs are likely to produce depression and low self-esteem and may contribute to feelings of alienation from the school environment. For some adolescents, the time spent in these kinds of work settings is associated with the development of cynical attitudes toward work and greater acceptance of unethical practices by workers.

Other researchers have emphasized the diversity of work experiences and the potential benefits of certain kinds of work. Students who are able to find and keep a good job may feel more confident about themselves and their promise for future employment. When the work does not involve too many hours, and involves skill development that young people see as related to their future career direction, the experience is associated with higher levels of well-being and fewer problem behaviors. For girls, the perception of continuity between school and work and the feeling that work improves one's school performance had an especially positive relationship with mental health and well-being (Staff, Messersmith, & Schulenberg, 2009).

The transition at high school graduation is a clear societal cue that career decision making has to begin, placing the developmental task of career choice squarely in later adolescence. In order to achieve this task, four related processes must unfold: becoming aware of and concerned about career decision making, actively engaging in the process of self-understanding, actively examining career options, and analyzing the fit between the two (Savickas, 2011). Unfortunately, many young people leave high school with negative expectations about their career search because they have already experienced unemployment and perceive the job opportunities in their community to be very limited. What is more, many high school students focus narrowly on striving to be admitted to college, having done relatively little work on career exploration. They come to college with only a very vague idea about how their college education will be related to a career choice (Xiao, Newman, & Chu, 2016).

Factors Influencing Career Choice

Career choice is influenced by many factors (see FIGURE 10.4 ▶). Personal experiences and work on identity development contribute to career choice. Career choice is also influenced by a network of individual, socioeconomic, familial, school, peer, mentor, and neighborhood factors. These career decisions are embedded in a sociohistorical time period during which the labor market, economic conditions, and opportunities for various types of work will vary.

High school and college students say that individual factors, such as abilities, achievement needs, attitudes, and self-expectancies, most strongly affect their career decision making. They tend to think that familial, societal, and socioeconomic factors have little or no impact. This is contrary to social science research evidence. Family factors play a key role in shaping educational aspirations and occupational goals. Societal and socioeconomic conditions are major factors influencing the job market and the chances of both employment and advancement. Students who have a clearer understanding of the critical social and economic factors that influence the labor market are better able to consider career alternatives and to analyze the steps they need to take in order to achieve their career goals (Diemer & Blustein, 2006; Dietrich, Parker, & Salmela-Aro, 2012). In the following sections we highlight three of these influences: family environment, educational contexts, and gender.

FIGURE 10.4 ▶ FACTORS AFFECTING CAREER CHOICE IN LATER ADOLESCENCE

Family Environment. A supportive, secure socioemotional family environment plays a key role in fostering effective career decision making. Parents influence their adolescent's career decision making through the values and expectations they convey about educational attainment, their own work activities and work ethic, and the way they encourage their children to develop and master their interests, talents, and abilities. Parents influence their children's school achievement from early childhood through the high school and college years. Parents are role models for their children, providing information about the specific kinds of work they perform. They provide opportunities for their children to hear the way they talk about their work and to observe their parents' success or frustration in the labor market (Staff, Messersmith, & Schulenberg, 2009). Most later adolescents continue to look to their parents for advice, resources, and emotional support throughout these years.

Differences in family resources result in diverging educational backgrounds, which have direct implications for the kinds of careers one is prepared to enter. We have addressed the educational achievement gap related to family income in earlier chapters, beginning with the topic of school readiness in chapter 6. In the period of early adolescence, children from low-income families and from families in which the parents did not graduate from high school are more likely to drop out of high school and less likely to be enrolled in postsecondary education. A national longitudinal study followed 15,000 students beginning at their sophomore year in high school. Ten years later, 14 percent of those in the lowest SES families had a bachelor's degree or higher; 60 percent of those in the highest SES families had a similar level of education. Even when students who scored in the top quartile in mathematics achievement in high school were compared, only 41 percent of those from the lowest SES families graduated from high school compared to 74 percent of those in the highest SES families (U.S. Department of Education, 2015). These data highlight a substantial impact of family income on educational attainment, which, of course, has implications for career choices and occupational opportunities. The gap in academic achievement between the children of families with the most and the least resources has been widening, at least as data for children born in the 1970s and in 2001 can tell us. Among those enrolled in college, about two thirds of students from families in the top income quartile graduate; fewer than one quarter of students from families in the bottom quartile graduate (Bailey & Dynarski, 2011; Dynarski, 2015; Reardon, 2011). Differences in neighborhood poverty, family income, families' ability and willingness to support occupational exploration, and the parents' own educational and occupational attainment influence their children's educational access, persistence, and career decision-making process.

Education and Career Choice. Career advancement and the associated earnings are closely linked to levels of educational attainment. The metaphor of a pipeline is often used when thinking about educational attainment and career choice. As students move along the educational pipeline, their aspirations and intentions as well as their understanding of the requirements for educational advancement impact their decisions. One step along the pathway is students' intention to graduate from high school. For those who do not graduate from high school, career development is a bumpy path. In 2015, the unemployment rate for those who had dropped out of high school in the preceding year was 30 percent (Bureau of Labor Statistics 2016a).

While in high school, some students benefit from career counseling, assessment, and academic advising about postsecondary alternatives, but many do not have access to these resources. Preparation for the post-secondary transition is very uneven. For example, in a study of high school students in California, only about one third knew all of the curricular requirements for attendance at one of California's public colleges and universities, and fewer than 1 percent of students' parents knew these requirements. This is particularly disturbing in that California has one of the more fully articulated educational state systems with a well-developed set of application and transfer guidelines (Kirst & Bracco, 2004). Students who attend a well-resourced high school where most students attend college are likely to have access to a career resource center and individualized guidance about college applications and admissions. Students who attend less advantaged high schools have little access to guidance about postsecondary educational or employment avenues. In contrast to the myth that education is the great equalizer for opportunity, evidence is accumulating that social inequality is reproduced and extended through the organization and inequality of public schooling (Bailey & Dynarski, 2011; Dynarski, 2015).

Table 10.1 Median Annual Earnings of Men and Women 25–34 Years, 2014, by Level of School Completed and Sex

	Average Annual Income ($)	
Education	**Men**	**Women**
Less than high school completion	25, 000	19,950
High school graduate	32,970	25,000
Some college, no degree	35,790	28,040
Bachelor's degree or more	57,890	49,810

Source: Table 502.30 National Center for Education Statistics, 2015d.

College is becoming an increasingly essential aspect of career development. In 2014, 68 percent of high school graduates in the United States were enrolled in some type of postsecondary institution, 64 percent of men and 73 percent of women. This compares to 49 percent of high school graduates in 1980 (National Center for Education Statistics, 2015b). Despite the large number of students who attend some type of college, many do not complete a degree. In 2015, 32.5 percent of the population ages 25 and older had a college degree or more. This percentage varied greatly by race/ethnicity: African Americans, 22.9 percent; Asian Americans and Pacific Islanders, 52.9 percent; European Americans, 36.2 percent; Hispanic/Latinos, 15.5 percent; American Indian/Alaskan Native, 19.8 percent; and two or more races/ethnicities 30.6 percent (National Center for Education Statistics, 2015c).

Table 10.1 shows the average annual income on the basis of educational attainment for men and women who were 25 to 34 years old in 2014. Educational attainment has a significant relationship to annual income. As the data indicate, however, educational achievement does not result in the same economic advantages for men and women. At all levels, women earn less than men, and women with 1 to 3 years of college but no degree earned less on average than men who were high school graduates (National Center for Education Statistics, 2015d). As more and more women earn college degrees and compete for higher paying jobs, the U.S. corporate environment appears to be getting quite a bargain by paying them less than their equally educated male colleagues. What is more, at every level of educational attainment, all groups are earning less in the most recent year than they were in 2009. The nature of the labor market leaves young people exposed to a range of what have been labeled as "bad jobs" (Kallenberg, 2011). Many are part-time, routine, with minimum wages and little job security.

The impact of educational experiences on subsequent career development goes beyond whether one plans to attend college or not. Vocational coursework of a specific nature, such as agricultural training, an emphasis on math and science courses, taking the sequence of courses that are required for college admission, and frequent conversations with teachers about one's work-related decisions are all associated with higher income and more stable work records after high school. Development of work-related habits such as attention to detail, the ability to plan and follow through on complex tasks, persistence in the face of difficulties, and communication skills are all part of the eventual success in finding a satisfying career path. Identity formation, self-insight, and active clarification of work values are all related to greater career confidence and more mature career decision making (Patton & McMahon, 2014).

Gender-Role Socialization and Career Choice. Gender-role socialization shapes career decisions through two significant psychological factors: (1) perceptions of ability and (2) career-related values and goals. First, as a result of socialization, men and women tend to form different expectations about their ability to succeed at various career-related skills. Self-expectancies about the ability to fulfill the educational requirements and job duties of specific careers are a major factor in determining career choices. Recall from chapter 8 (Middle Childhood) the discussion of parents' expectations about their children's competence in certain skill areas and its relation to the child's own perceptions of competence. In a longitudinal study, mothers' gender-stereotyped beliefs about their young child's math and science abilities predicted their child's self-perceptions of math and science self-efficacy 2 years after high school. Mothers' predictions of their child's ability to succeed in a math-oriented career was a significant predictor of their college-age child's career choice (Bleeker & Jacobs, 2004).

In the process of career decision making, strong gender-typed conceptualizations of the job demands of specific careers intervene to screen out some alternatives and highlight others. For example, there is a clear path from belief in one's competence in math to aspirations about careers in math, science, and engineering (Correll, 2001). Gendered beliefs about mathematics competence, influenced in part by parental expectations, teachers' evaluations, and career guidance advisors, may contribute to the persistent gender divide with respect to women enrolling in university and graduate programs in mathematics, physics, and engineering. In addition to gender socialization, persistent gender stereotypes attach to images of femininity. For example, in one study the same woman was dressed in a neutral outfit and in a "feminine" outfit. When being rated by both male and female students as a potential employee for a student IT job, when the woman was dressed in the feminine clothing she was considered as having less adequate computer skills, being less likely to succeed at a computer task, and as being less intelligent (Fleischman et al., 2016). Social feedback attached to one's gender image can impact one's own self-confidence and self-evaluation.

A national survey of students entering college in 2015 asked freshmen to rate their ability in a variety of areas. Even though women are now more likely than men to enter college and graduate, female students were less confident about their academic ability, less confident about their computer skills, and less confident about their mathematical abilities than male students (CIRP, 2015). Studies of career choice or career aspirations find that women with a strong sense of their own goals, an awareness of their personal needs, and an ability to cope realistically with stress are more likely to adopt a nontraditional career choice. A growing number of supportive groups, many funded in part by the National Science Foundation, have formed to encourage and mentor young women who have ability in mathematics to pursue college majors and occupations in the fields of science, mathematics, and technology.

Second, as a result of socialization, women and men are likely to establish different value hierarchies, reflecting different long-range life goals. Experiences in middle childhood set in motion images about one's preferred work and lifestyle in adulthood. In a study that followed children from about age 10 into their mid-twenties, researchers found that boys whose mothers had more traditional views about women's roles were more likely to choose traditional male occupational roles. Girls who spent more time with their fathers were more likely to enter nontraditional female occupations (Lawson, Crouter, & McHale, 2015). Among later adolescents, young men tend to prefer "jobs characterized by high salaries, power or influence over others, opportunities for advancement or achievement, risk taking, challenging tasks, a high level of responsibility, and a high level of prestige" (Weisgram, Bigler, & Liben, 2010, p. 779). Young women prefer "jobs that allow them to work with or help others, develop their knowledge or skills, and spend time with family" (Weisgram et al., p. 779). For example, one study compared what college students wanted from their careers, referred to as *work goals*, with what they thought certain careers might allow them to achieve, called *goal affordances*. Students who thought a career would help them achieve their work goals were also more interested in those careers (Morgan, Isaac, & Sansone, 2001). Women rated interpersonal goals as more important and high pay and high status goals as less important than did men. Both men and women viewed careers in physical and mathematical science as offering less in the way of interpersonal goals and more in the way of salary and status. As a result, women were less interested in careers in physical and mathematical science and less likely to identify those fields as career choices (Diekman, Brown, Johnston, & Clark, 2010). An additional factor is that women often encounter cultural stereotypes that imply that women are not as competent or well-suited for mathematics and science as men, which can undermine their motivation to persist in these fields (Zhang, Schmader, & Forbes, 2009). The internalization of gender-related goals is directly related to how motivated a young man or woman is in pursuing a career that promises to allow her to attain those goals (Evans & Diekman, 2009). Other contextual factors can also impact a decision to enter a gender atypical career. For example, in a study of U.S. teens, those boys who had a large number of female friends, whose parents were well-educated, and who expected growth in the field were more likely to aspire to a female-oriented career (Hardle, 2015).

The consequences of gender-role socialization for career choice can be seen in the distribution of men and women in the labor force (Bureau of Labor Statistics 2016a). Although there are many areas where men and women are equally involved, patterns of gender differentiation are quite notable. For example the large majority of those working in fields of preschool education, elementary or middle school teaching, special education, nursing, and office/administrative support are women. The large majority of those working as firefighters or police, or in engineering, computer programming, transportation, construction, and natural resources, are men.

Career Decision Making

The idea of **career decision making** must be evaluated in light of rapid changes in the nature of work. The pervasiveness of the two-earner family lifestyle, the increased likelihood of multiple job and career changes over the life course, and the constant reconfiguration of the job market—especially the trends toward downsizing, workforce reductions, retraining, and outsourcing are all factors that impact a young person's thinking about career choice. The idea of occupational choice should not be confused with choice about labor market participation. Although they may have a wide choice in the kind of work they will do, most people in the United States do not have a choice about whether to work or not. In fact, about 6 percent of young people in the 20 to 24 age range have more than one job (U.S. Bureau of Labor Statistics, 2015c, Table 36).

Career choice reflects a central component of a person's emerging identity. For some young people, occupational choice is a reflection of continued identification with their parents. They may select the same job or career as that of one of their parents, or they may select a career because it reflects their parents' aspirations for them. Little personal choice is involved. For some young people, primarily women, there continues to be a path of primary identification with the roles of wife and mother, with only secondary investment in the labor market. Many of these women, especially those who marry and have children after high school, return to school or to technical training in their 30s and 40s in order to pick up the thread of career development, either as a result of divorce or when their children get older. Increasing numbers of men and women realize that their occupational career will need to be coordinated and integrated with that of their spouse. In anticipation of a dual-earner lifestyle, young people begin to screen their career aspirations through the lens of the

compatibility of job demands with family commitments and personal aspirations.

Many people assume that the younger a person is when he makes a career choice, the better. Most career development professionals, however, advise that a decision about a career be delayed until later adolescence or early adulthood. The concept of **career maturity** suggests that with increased cognitive and affective development, a person develops decision-making strategies, gains access to information, and achieves a degree of self-insight that permit a realistic and consistent choice (Schmitt-Rodermund & Silbereisen, 1998). A person who delays the decision has a clearer sense of their adult interests and goals. By delaying the career decision, one also has more opportunities to explore alternative work scenarios and to understand more about the labor market.

Nonetheless, high schools, colleges, and various industries urge young people to make career choice decisions as early as possible. Thus, some of the tension that later adolescents experience in connection with a choice of career is a product of the lack of fit between socialization pressures and their own developmental timetable. With the increased likelihood of living to be 80 years old, there is no great rush to decide on a career by age 20. In the United States, the average person with a bachelor's degree is likely to have many jobs between the ages of 18 and 32, more in the period of later adolescence and fewer in their later 20s and 30s. These jobs may or may not be part of a coherent career. For example, many college students work in restaurants and local shops, but these jobs are not part of their intended career path. Other later adolescents work in a job they expect to be temporary, just to earn enough money to buy a car or pay their insurance until they are ready to move on to something new.

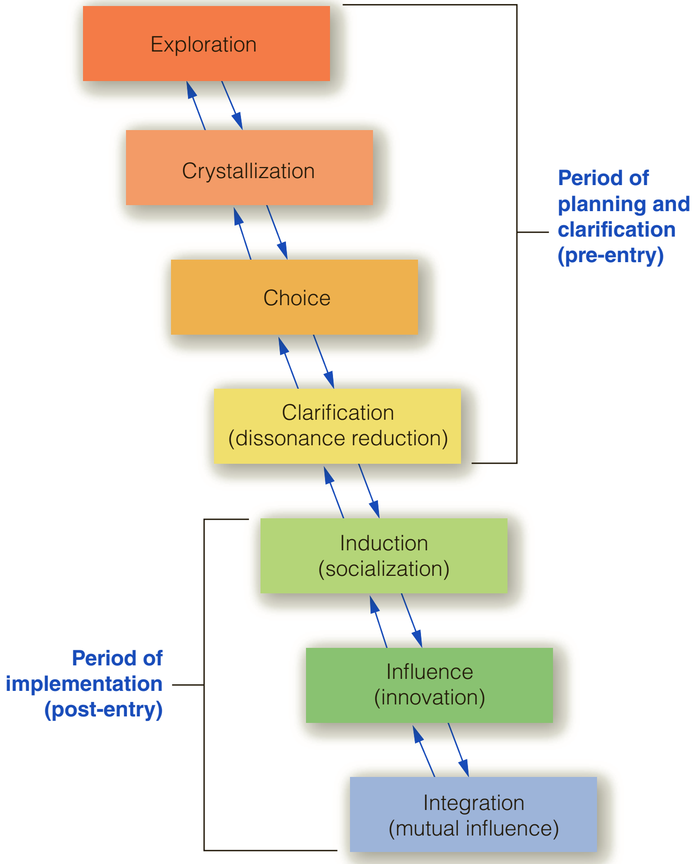

FIGURE 10.5 ▶ SEVEN PHASES OF CAREER DECISION MAKING

Source: Based on Tiedeman and O'Hara, 1963.

Phases of Career Decision Making. The literature on career decision making provides a variety of models that suggest phases or steps in a complex process including: an initial awareness of one's interests and abilities; identification of career values and goals; engagement in information gathering about the world of work and the requirements of specific occupations; exploration of work experiences; making an eventual commitment to a career path; and continuously evaluating the fit or lack of fit between these experiences and one's emerging identity (Dietrich, Parker, & Salmela-Aro, 2012; Gadassi, Gati, & Dayan, 2012). A career decision depends on the outcomes of several tasks during early and later adolescence and early adulthood. With effective problem solving, the person gains increased control over life events and is better prepared to meet the challenges of the next phase of decision making.

One such model, developed by Tiedeman and colleagues (Tiedeman & Miller-Tiedeman, 1985; Tiedeman & O'Hara, 1963), identifies seven **phases of career decision making**; the first four emphasize planning and clarification, whereas the last three emphasize implementation (FIGURE 10.5 ▶). The model illustrates how making career-related decisions helps to clarify one's occupational identity and, at the same time, uses the context of work to promote new learning about other aspects of the self. The model reflects an individual's capacity for ongoing adaptation and change. At each phase in the process, people can redefine the self and transcend the conditions of the work environment to change their minds (Miller-Tiedeman, 1999).

In the **exploration phase**, the person realizes that a career decision must be made and therefore begins to learn more about those aspects of the self and the occupational world that are relevant to the impending decision. This is the point at which many young people use computer programs that help them identify their interests and abilities as well as the fit between these preferences and various occupations. The person begins to generate alternatives for action. Uncertainty about the future and the many possible alternatives are accompanied by feelings of anxiety. Concerns about future educational and career decisions constitute a major source of worry for college students. Many colleges and universities offer access to computer software programs including the Strong Interest Inventory, the Holland Self-Directed Search, and My Next Move sponsored by O'Net from the Bureau of Labor Statistics. These programs support exploration by incorporating a focus on a person's interests, talents, and values with descriptions of occupations and their features, requirements, and opportunities.

In the **crystallization phase**, the person becomes more aware of the alternatives for action and their consequences. Conflicts among alternatives are recognized, and some are discarded. The person develops a strategy for making the decision,

Phovoir/Shutterstock.com

Paul is using the university's career exploration software to identify careers that are a good match for his interests and talents.

in part by weighing the costs and benefits of each alternative. This is a phase when a person might engage in volunteer work, short internships, or summer jobs that help to clarify the nature of the work and the fit or lack of fit with their own temperament, talents, and values.

In the **choice phase**, the person decides which action alternative to follow. The decision is solidified in the person's mind as he or she elaborates the reasons why the decision is beneficial. There is a sense of relief and optimism as the person develops a commitment to executing the decision. For college students, the choice phase might be the decision about a major. Of the students entering college as freshmen in 2012, 85 percent said that an important reason for going to college was to be able to get a better job (Eagan et al., 2015*)*. For those who do not attend college, the decision might involve an apprenticeship or applying for a job that involves some extended training. The choice phase implies a willingness to invest time and effort in order to excel in this career.

In the **clarification phase**, the person more fully understands the consequences of the commitment to the decision that has been made. A person may tell others, including family and friends, about the decision, which may prompt the need to justify or explain the decision. There may be unexpected implications of the career choice. For example, the career decision may require additional education or training; the person may begin to be aware of some social advantages or disadvantages of the career; or the jobs that are open in the career may require moving to a new town. A person's self-concept is modified by the commitment to a career path and the desire to create congruity between one's decision and the demands that are likely to accompany that decision. For example, among students who made a commitment to an engineering major, the intention to persist was tested after two, three, and four semesters. The strongest predictor of commitment to persist was the student's self-efficacy. Having encountered the challenges and demands of the major, these students had confidence in their ability to succeed (Lent et al., 2015).

During the **induction phase** the person encounters the new career environment. The person wants to be accepted and looks to others for cues about how to behave. The person identifies with the new group and seeks recognition for his or her unique characteristics. If the choice is a good fit, the self-image is gradually modified as the person begins to believe in the values and goals of the new group. However, in some cases the person experiences incongruities between the demands of the career and personal values or goals. The work environment is not supportive; the work is more difficult, more tedious, or less rewarding than expected; or the person longs for opportunities that are not possible in this career. The model suggests that the person might start again with a new plan.

In the **influence phase**, the person is very much involved with the new group. The person becomes more assertive in encouraging the group to perform better. The person also tries to influence the group to accommodate some of his or her values. The self is strongly committed to group goals. During this phase, the group's values and goals may be modified to include the orientation of the new member. In some cases, these efforts to influence the group do not work out. Ideas that the worker brings from his or her education and training are rejected. The power hierarchy in the profession resists change. As the person matures, values and goals change, resulting in a new idea about one's occupational path.

Finally, in the **integration phase**, the group or the profession makes a more lasting investment in the person, whether by offering tenure, a long-term contract, licensure, or some other form of commitment. This process brings about a new degree of allegiance to the career and the specific work environment. The person now has a more complete understanding of the goals and operation of the group and has incorporated features of the career into his or her identity. A true collaboration between the new member and the group is achieved. The new member feels satisfied and is evaluated as successful by the self and others. Although this phase implies a degree of stability, conditions may arise that require reevaluation. Economic downturns may lead to layoffs; new government standards may require retraining; changes in the ownership or leadership of a company may result in a new work culture. In each of these conditions, the person may find that it is time to review and revise the career decision.

This model emphasizes continuous interaction between the individual and the work context. At first, interaction is necessary to clarify the person's talents and choice of career. Later, it is necessary to achieve a satisfactory level of adaptation to the work environment. At each juncture, whether the decision relates to college major, occupation, job change, or career redirection, effective decision making involves all seven phases. Each career is a unique story in its own right.

Career Decision-Making Self-Efficacy

The concept of career decision-making self-efficacy is widely used in the field of vocational education and development to highlight the role of a person's emerging confidence in the ability to make an effective career choice. Albert Bandura introduced the concept of self-efficacy to refer to the confidence that a person has that he or she can meet the standards for performance in a particular domain. We discussed self-efficacy in some detail in chapter 8, as a component of the developmental task of self-evaluation. Judgments of self-efficacy stem from four sources: prior experiences of success or failure in a specific domain, encouragement or discouragement from others (verbal persuasion), vicarious experiences of watching others succeed or fail, and the physical state of arousal that accompanies being engaged in the task.

Career **decision-making self-efficacy** includes assessments about whether one can make an accurate self-appraisal of one's abilities, gather relevant occupational information, formulate appropriate goals, make plans to achieve those goals, and solve the problems that pose barriers to the achievement of goals (Betz, 2001). For college students, the sense of career decision-making self-efficacy is closely tied to confidence in other domains, the most important of which is leadership. Students who believe that they have strong leadership abilities and who have had positive leadership experiences are also more confident about their ability to make effective career decisions. In addition, confidence in science, math, writing, using technology, and cultural sensitivity all contribute to career decision-making self-efficacy (Paulsen & Betz, 2004). Many courses and programs are introduced on college campuses to help support students' career decision making. The idea that self-efficacy about career decision making can be enhanced through deliberate interventions has guided many of these programs, resulting in measurable improvements in career confidence, especially for students who are unsure or highly anxious about their career direction (Betz, 2007).

The Impact of the Labor Market on Career Decision Making

Each cohort faces unique labor market conditions as they enter the career search process in later adolescence and early adulthood. Characteristics of the contemporary labor market may contribute to new difficulties as well as new opportunities that young people face as they attempt to move through the first four phases of Tiedeman's model.

- The increasing number of jobs and careers available make the exploration phase more difficult.
- As a result of changes in technology and organizational structure, some skills become obsolete and some job markets dry up. A career may become obsolete in the time it takes a young person to prepare for it.
- As established firms lose their identities in corporate mergers, identification with a particular company ceases to be appropriate.
- As most large companies go through restructuring and downsizing, the people who are left are asked to do more tasks of a greater variety. In addition to one's special area of training, it is important to develop support skills including data management, literature search skills, and verbal and written communication skills.
- New careers emerge at a rapid pace. From the time one enters the choice phase to the time one enters the influence phase, new kinds of work roles may become available.
- Career paths are less clear than they once were. Young people are being advised to expect three or four career changes in their lifetime. They may end up moving from the private to the nonprofit sector, from business to education, or from service provider to entrepreneur.
- The cost of living—especially the costs of housing, health care, and education—introduces concerns about the amount of money that will be needed to live comfortably. In addition, student loans must be repaid. Worries about making money may interfere with effective career decision making. There are many "bad jobs" even for college graduates. These jobs are defined as "those that pay less than $37,000 per year (in inflation-adjusted 2010 dollars); lack employer-provided health insurance; and have no employer-sponsored retirement plan." According to this definition, in 2010, 24 percent of all workers were in bad jobs. The percentage of workers in bad jobs was higher at all levels of educational attainment in 2010 than it was in 1979 (Schmitt & Jones, 2012).

Given the complexity of the world of work, **career indecision** is common in later adolescence. In contrast to those later adolescents who know what career they plan to enter, there are two different patterns of career indecision. One is a developmentally normal state that results from a lack of work experience, inadequate information about the world of work, and continuing emergence of personal identity. The other is considered to reflect chronic indecision, related to a pervasive lack of self-efficacy, dependency, and more serious identity confusion (Guay, Ratele, Senécal, Larose, & Deschênes, 2006).

Ideally, one's choice of occupation is the result of personal experimentation, introspection, self-evaluation, fact finding, and intuition. In order to make a career choice, people may first choose to pose difficult questions to themselves about their skills, temperament, values, and goals. When they make a decision based on this kind of personal evaluation, they are likely to see their careers as a well-integrated part of their personal identities rather than as activities from which they are alienated or by which they are dominated.

With advances in science, microbreweries have become a new option for careers. In this image, the French brewmaster demonstrates the latest techniques in beer making to students who are enrolled in a college course.

FURTHER REFLECTION: *Describe some of the ways that career decision making influences identity development and the ways that identity development may influence career decisions.*

How far along are most students in their career decisions by the time they enter college? By the time they graduate from college?

What are the most valuable experiences students have in later adolescence that support career decision-making?

The Psychosocial Crisis: Individual Identity Versus Identity Confusion

OBJECTIVE 5 Define and describe the psychosocial crisis of later adolescence, individual identity versus identity confusion; the central process through which this crisis is resolved, role experimentation; the prime adaptive ego quality of fidelity to values and ideals; and the core pathology of repudiation.

The psychosocial crisis of later adolescence is individual identity formation versus identity confusion. This crisis results from the enormous difficulty of pulling together the many components of the self—including changing perspectives on one's beliefs and values as well as new and changing social demands—into a unified image that can propel the person toward positive, meaningful action. As part of this process, a young person struggles to formulate a worldview, an outlook on those goals and values that are personally important and to which the person is willing to make a commitment. Over the period of later adolescence, whether in the context of college, the military, or in other work and community settings, young people begin to examine the beliefs and goals they may have internalized from childhood. Through self-reflection, role experimentation, and feedback from significant others, later adolescents make decisions about whether these beliefs and goals are still meaningful as they look ahead to the future.

Individual Identity

Erik Erikson provided a comprehensive treatment of the meaning and functions of **individual identity**, from his inclusion of this concept in the theory of psychosocial development in 1950 to his analysis of American identity in 1974 (Erikson, 1950, 1974). His notion of identity involves the integration of past, present, and future. From the past, young people undertake a process of reexamination of childhood identifications. From the present, young people identify and evaluate their talents, interests, and abilities. From the future, there is an articulation of valued life goals and aspirations. These three sources of identity content have to be woven into a meaningful sense of a purposeful self. The major works in which he discussed identity are the article "The Problem of Ego Identity" (Erikson, 1959) and the book *Identity: Youth and Crisis* (Erikson, 1968).

The construct of personal identity is not the same as the self-concept. The self-concept is a cognitive integration of one's physical qualities, personality traits, motives, and strivings, as well as an assessment of how one is viewed by others. The idea of personal identity is embedded in a lifespan perspective, reflecting the sense of meaning, purpose, and related commitments one embraces as one makes the transition from childhood into adulthood. Our discussion, which is grounded in Erikson's writings, is broadened to include the ideas of others whose work extends and operationalizes the concept of identity and links it to a sense of purpose (Crocetti, Rubini, & Meeus, 2008; Damon, 2008; Kroger, 2004; Lawler, Thye, & Yoon, 2009; Schwartz, 2001; Schwartz, Luyckx, & Vignoles, 2011).

Later adolescents are preoccupied with questions about their essential character in much the same way that early-school-age children are preoccupied with questions about their origins. In their efforts to establish an identity, later adolescents must take into account the bonds that have been built between them and others in the past as well as the direction they hope to take in the future. Identity serves as an anchor point, providing the person with an essential experience of continuity in social relationships:

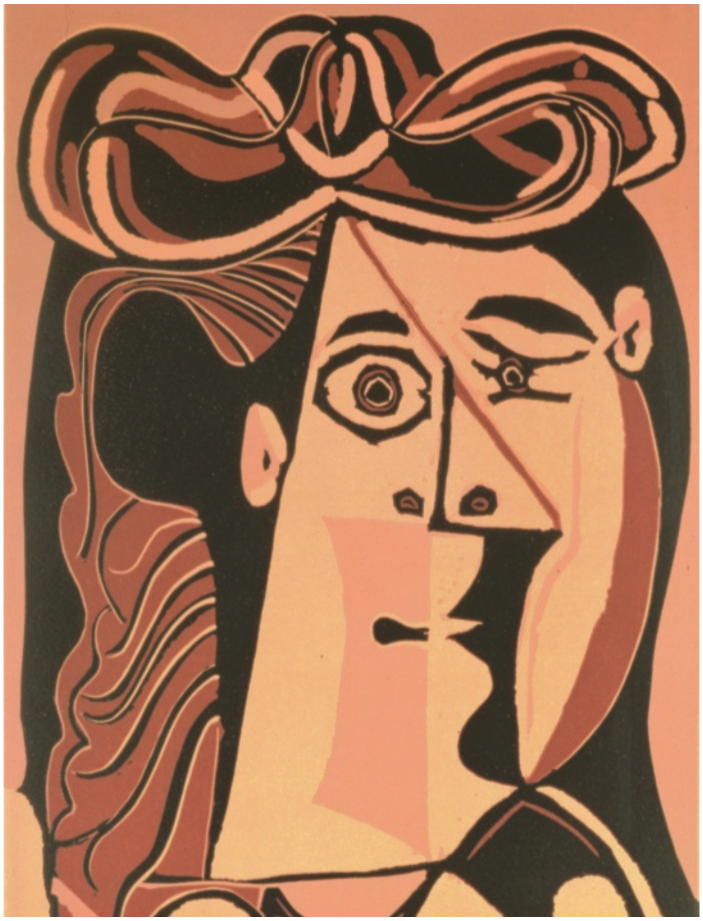
> The young individual must learn to be most himself where he means the most to others—those others, to be sure, who have come to mean most to him. The term identity expresses such a mutual relation in that it connotes both a persistent sameness within oneself (self-sameness) and a persistent sharing of some kind of essential character with others. (Erikson, 1959, p. 102)

The Private and Public Faces of Identity

As the preceding quotation suggests, identity achievement is associated with an internal sense of individual uniqueness and direction accompanied by a social or community validation about the direction one has chosen. Thus identity includes both a private and a public self. The **private self**, often described as a *sense of self*, refers to one's uniqueness and unity, the subjective experience of being the originator of one's thoughts and actions and of being self-reflective. Through the private self, one recognizes the values and beliefs to which one is committed, and the extent to which certain thoughts and actions are consistent with those beliefs. The private, subjective sense of self, which develops over the course of the life span, includes four basic elements (Blasi, 1991; Glodis & Blasi, 1993):

- A sense of *agency*—Being the originator of thoughts and actions.
- A sense of *unity*—Sensing that one is the same basic self from one moment or one situation to the next.
- A sense of *otherness*—Recognizing the boundaries between the self and others.
- A sense of *decentering* or *distancing*—Reflecting on oneself so that one can recognize and own one's thoughts and actions.

The **public self** includes the many roles one plays and the expectations of others. As young people move through the stage of later adolescence, they find that social **reference groups**—including family members, neighbors, teachers, friends, religious



This image captures a contemporary sense of the search for individual identity: a young woman with a broad-rimmed hat, hair flowing, one eye looking outward to the world, and one turned inward on the self.

groups, ethnic groups, and even national leaders—have expectations of their behavior. A young person may be expected to work, attend college, marry, serve the country in the military, attend religious services, vote, and provide economic support for family members. Persistent demands by meaningful others result in decisions that might have been made differently, or not made at all, if the individual were surrounded by a different configuration of social reference groups. In the process of achieving personal identity, one must synthesize the private sense of self with the public self derived from the many roles and relationships in which one is embedded.

The Content and Evaluation Components of Identity

The structure of identity has two components: content and evaluation. The *content* includes what one thinks about, cares about, and believes in, and the traits or characteristics by which one is recognized and known by others. Erikson suggested that identity was achieved by finding one's sense of direction with respect to salient roles and values, especially vocational decisions, political and religious ideologies, sexual expression and gender role, and interpersonal values. In many measures of identity formation, these domains comprise the foundational content areas (Kroger, 2012). The second structural component of identity, *evaluation*, refers to the significance one places on various aspects of the identity content. Even though most people play many of the same roles, their identities differ in part because they place different values on some of these roles. Some people are single-minded, placing great value on success in one domain, such as their vocational goals, and little value on the others. Other people strive to maintain a balance in the roles they play; they consider themselves successful if they can find enjoyment in a variety of relationships and activities.

A person's assessment of the importance of certain content areas in relation to others influences the use of resources, the direction of certain decisions, and the kinds of experiences that may be perceived as most personally rewarding or threatening. College students, for example, may differ in whether academic success and professional preparation or interpersonal success is most central to their sense of identity. Students who are more concerned about academic success take a different approach to the college environment, become involved in different kinds of activities, and have a different reaction to academic feedback than do students who are more concerned about making friends and having new kinds of social and interpersonal success (Green & Hill, 2003).

Both the content and evaluation components of identity may change over the life course. In later adolescence, the focus is on integrating the various sources of content and determining which elements have the greatest salience. This is a major accomplishment that requires self-awareness, introspection, and the active exploration of a variety of roles and relationships. Insight into this process is provided in the case study of Houston A. Baker, Jr. However, the identity that is formed at the end of this period is often very abstract because later adolescents have not yet encountered many of the responsibilities, pressures, and conflicts of adult life. The ideological framework of identity has not yet been forged in the flames of reality.

— **CASE STUDY** Houston A. Baker, Jr. —

A poet and literary scholar tells of the impact of one of his college professors on his personal identity.

He intrigued us. Slowly puffing on the obligatory pipe, he would chide us for the routineness of our analyses of revered works in the British and American literary canons. He wore—always—a tie and tweed of Ivy provenance, and at the end of the first session of his "World Literature" course at Howard University in the fall of 1963, I had but one response—I wanted to be exactly like him.

The task was to prove myself worthy. I labored furiously at the beginning assignment—an effort devoted to Marvellian coy mistresses and pounding parodies thereof. The result was a D and the comment: "This is a perfunctory effort. You have refused to be creative. There are worlds on worlds rolling ever. Try to make contact with them." I was more than annoyed; I was livid. Who did he think he was? I'd show him. My next essay would reveal (cleverly, of course) that I didn't give a tinker's dam for his grade or his comments. "Creative"—indeed!

My second essay might properly have been entitled: Love's labor loosed on William Blake. I strained to see every nuance of the "Songs of Innocence." I combed the poems for every mad hint that would help forward my own mad argument. I never turned my eyes from the text as I sought to construct the most infuriating (yet plausible) analysis imaginable. I felt my feet dancing to Muhammad Ali rhythms as I slaved away, darting logical jabs at Professor C. Watkins who would (I was certain) be utterly undone when I threw my irreverent straight right. The paper came back with the comment: "This is a maverick argument, but stubbornly logical—A–" Bingo! The grade in itself gave me almost enough courage to seek him out during office hours—but not quite. I corralled a friend to make the pilgrimage with me.

He was extraordinarily gracious on the mid-autumn afternoon when we had our first long talk. "Come in, Mr. Baker—Miss Pierce. How are you?" His tie was loose; he was reared back in his desk chair. There was a clutter of papers and blue books, and they provided a friendly setting for a two-hour conversation.... We were thrilled that he considered us (potentially) enough like him to invite us to visit him and his wife two weeks hence—for dessert.

The evening surprisingly took on (in my youthful imagination) the cast of Greenwich Village "Beats" and verboten revelations. The greatest stimulation, however, came when he played the Library of Congress recording of T. S. Eliot reading "The Wasteland." In that moment, I became, willy-nilly, a party to "modernism" in its prototypical form. I was surprised and delighted. I had heard nothing like it before. The Eliotian reading initiated my habit of "listening" for poems rather than "looking" for them.... I stepped into a late fall evening with an entirely new sense of myself and of "worlds on worlds rolling ever."

CASE ANALYSIS Using What You Know

1. Analyze the elements of the identity process that are evident in this case.
2. Describe some of the characteristics of Professor Watkins that made him a model for identification for Houston Baker.
3. Summarize aspects of the college environment that are likely to stimulate the identity process.
4. Have you ever had an intellectual experience that gave you a "new sense of yourself"? Explain the combination of factors that came together to permit this to happen.

Identity Status

Identity development takes place in historical and cultural contexts. During early and later adolescence, young people are aware of the age-graded expectations that exist in their families and communities, typically structured around specific tasks and roles, including educational attainment, occupation, intimacy, marriage, and childrearing. In most modern societies, each of these areas presents a variety of opportunities or possible paths as well as some constraints about which paths are possible given certain personal, financial, and cultural resources. In later adolescence, the **identity process** includes examining alternatives, selecting goals in these domains, making personal and interpersonal commitments to achieve these goals, and taking the active steps to achieve them (Nurmi, 2004). Throughout the chapter we have described contemporary circumstances that are prolonging the transition into adulthood, especially expectations for additional education, more diverse career alternatives, delayed entry into marriage, and less attachment to formal religious organizations. For all these reasons, one might expect the work on personal identity to take longer, require more time for exploration, and involve more revisions than may have been the case 40 years ago or in some other more traditional societies (Schwartz et al., 2013).

Identity formation is a dynamic process that unfolds as young people assess their competencies and aspirations within a changing social context of expectations, demands, and resources. A variety of potential resolutions of the psychosocial crisis of individual identity versus identity confusion have been described (Kroger, 2012; Kroger & Marcia, 2010). At the negative pole of the crisis, identity confusion or diffusion, the person is not able or possibly not willing to make any commitments to adult roles and values. At the positive pole, identity achievement, the person has made commitments to a defined set of values and goals.

Is it possible to compare later adolescents with regard to their progress in the formation of a personal identity? The concept of **identity status** is used to make these comparisons. It reflects different degrees of exploration and certainty about one's values and goals. One of the most widely used conceptual frameworks for assessing identity status was devised by James Marcia (1993, 2007). Drawing on Erikson's concepts, Marcia assessed identity status on the basis of two criteria: *crisis* and *commitment*. **Crisis,** sometimes referred to as exploration**,** refers to a period of trying out various roles, reviewing and sorting through one's options, and active decision making among alternative choices. **Commitment** consists of a demonstration of personal involvement and investment in the areas of occupational choice, religion, political ideology, and interpersonal relationships. On the basis of Marcia's interview, the status of respondents' identity development is assessed as identity achievement, foreclosure, moratorium, or confusion (see Table 10.2).

People who are classified as **identity achieved** have already experienced a crisis time and have made occupational and ideological commitments. They have struggled with experiences of uncertainty and have identified meaningful goals and values.

People who are classified as **foreclosed** have not experienced a crisis or a process of exploration, but demonstrate strong occupational and ideological commitments. Their occupational and ideological beliefs appear to be close to those of their parents. The foreclosed identity is deceptive. A young person of 18 or 19 who can say exactly what she wants in life and who has selected an occupational goal may appear to be mature. This kind of clarity of vision may impress peers and adults as evidence of a high level of self-insight. However, if this solution has been formulated through the wholesale adoption of a script that was devised by the young person's family, it may not actually reflect much depth

Table 10.2 **Relationship of Crisis and Commitment to Identity Status**

Status	Crisis	Commitment
Identity achievement	+	+
Foreclosure	–	+
Moratorium	+	–
Identity confusion	+/–	–

of self-understanding. It is not surprising to find that of the four identity statuses, those in foreclosure also score highest in authoritarianism, a tendency to rely heavily on the values and expectations of authority figures to decide what is right and how to behave (Ryeng, Kroger, & Martinussen, 2010).

People who are classified as being in a state of **moratorium** are involved in ongoing exploration and experimentation. Their commitments are diffuse. The moratorium status is typically an active, open time for gathering information and discovering how one fits in certain roles. In an extension of Marcia's model, the idea of exploration has been expanded—exploration in *breadth*, which involves engaging in a diversity of roles and relationships, and exploration in *depth*, which involves taking a closer look at some earlier commitments in order to assess their fit with current goals and values. Within this framework, moratorium status can look rather different for those who are in a period of open-ended searching possibly accompanied with anxiety over uncertainty, and those engaged in focused examination of existing commitments with an eye toward replacing earlier commitments with new ones (Meeus et al., 2010).

Finally, people who are classified as **identity confused** may have had a limited or nonexistent exploratory phase and are unable to make commitments. Marcia described the identity-confused group as having a rather cavalier, party attitude that allows members to cope with the college environment. He suggested that the more seriously confused persons (such as those described by Erikson, 1959) may not appear in his sample because they are unable to cope with college. More recent analyses of the confused status support this idea of two subtypes: *troubled confusion* refers to those who have unrealistic expectations, are afraid of making the wrong kinds of decisions, and experience high levels of anxiety about their indecision; and *carefree confusion* refers to those who appear to be unconcerned with making any identity commitments (Luyckx, Goossens, Soenens, Beyers, & Vansteenkiste, 2005). Those in the identity confused status look to others to define their sense of self and purpose.

Sometimes, a young person develops a **negative identity**, because the society has labeled the person in a negative way (Erikson, 1959). *Failure*, *good-for-nothing*, *juvenile delinquent*, *hood*, *gangster*, and *loser* are some of the labels that the adult society applies to certain adolescents. Terms such as *illegal alien* or *terrorist* define individuals as without value to society, and as such, impose a negative identity (Lawler, 2014). These labels disconnect individuals from meaningful social bonds or valued roles. The society creates a negative identity as "other" or "to be feared." The young person accepts such negative labels as a self-definition and proceeds to validate this identity by continuing to behave in ways that will strengthen it. Some young people grow up admiring people who have become very successful by following antisocial or criminal paths. Drug lords; gang leaders; leaders of groups that advocate hate, violence, and vengeance; and people who use elected political positions for personal gain are all examples of possible role models around which a negative identity may be formed.

A negative identity may also emerge as the result of a strong identification with someone who is devalued by the family or the community. A loving uncle who is an alcoholic or a clever, creative parent who commits suicide may stimulate the crystallization within the adolescent of a self-construal as one who may share these undesirable characteristics. Linda, for example, established the negative identity of a person going crazy:

> Her father was an alcoholic, physically abusive man, who terrified her when she was a child. . . . Linda, herself a bright child, became by turns the standard bearer for her father's proud aspirations and the target of his jealousy. Midway through grade school she began flunking all her courses and retreating to a private world of daydreams. . . . "I always expected hallucinations, being locked up, down the road coming toward me. . . . I always resisted seeing myself as an adult. I was afraid that at the point I stopped the tape [the years of wild experimentation] I'd become my parents. . . . My father was the closest person I knew to crazy." (Ochberg, 1986, pp. 296–297)

Identity Confusion

The maladaptive resolution of the crisis is identity confusion. Young people in this state are unable to make a commitment to any single view of themselves. They may be unable to integrate the various roles they play. They may be confronted by opposing value systems or by a lack of confidence in their ability to make meaningful decisions. Within the private, subjective self, some young people may reach later adolescence having difficulty accepting or establishing clear ego boundaries, or they may not experience feelings of agency. Individuals with identity confusion have been shown to have low self-esteem; they are more likely than individuals with other identity statuses to be influenced by peer pressures toward conformity; and they approach problem solving with tendencies toward procrastination and avoidance, which contribute to difficulties in adjusting to the college environment (Berzonsky & Kuk, 2000; Kroger, 2004). At an unconscious level, they may have incorporated two or more conflicting ideas about the self—for example, an abusive, harsh, rejecting powerful father and a wise, loving, nurturant, powerful grandmother—that stand in opposition to each other. Under any of these conditions, the demands for integration and synthesis of a personal identity arouse anxiety, apathy, and hostility toward the existing roles, none of which can be successfully adopted.

In comparison to the moratorium group, young people with a confused identity status are less conscientious, and are more likely to experience negative emotions and be more disagreeable. They have the lowest scores on multiple measures of well-being of all the identity status groups (Schwartz et al., 2011). They are generally not outgoing; rather, they describe themselves as self-conscious and likely to feel depressed. Their relationship with their parents is described as distant or rejecting. Difficulties in resolving earlier psychosocial crises—especially conflicts related to autonomy versus shame and doubt and initiative versus guilt—leave some young people with deficits in ego formation that interfere with the kind of energy and playful self-assertiveness that are necessary in the process of identity achievement (Marcia, 2006).

Dolores, an unemployed college dropout, describes the feeling of meaningless drifting that is associated with identity confusion:

> I have two sisters, and my father always told me I was the smartest of all, that I was smarter than he was, and that I could do anything I wanted to do . . . but somehow, I don't really know why, everything I turned to came to nothing. . . . I had every opportunity to find out what I really wanted to do. But . . . nothing I did satisfied me, and I would just stop. . . . Or turn away. . . . Or go on a trip. I worked for a big company for a while. . . . Then my parents went to Paris and I just went with them. . . . I came back . . . went to school . . . was a researcher at Time-Life . . . drifted . . . got married . . . divorced . . . drifted. [Her voice grew more halting.] I feel my life is such a waste. I'd like to write, I really would; but I don't know. I just can't get going. (Gornick, 1971)

A recent direction in the study of identity status has been to examine how identity processes relate to health-risk and health-promoting behaviors. Some studies have found a relationship between the *carefree* type of identity confusion and risky, reckless behaviors including rule breaking, use of dangerous drugs, risky sexual behaviors, and drunk driving (Schwartz et al., 2013). One interpretation of this link is that since these young people are not attached to any clear vision of purpose and meaning, they take risks with their health because they have nothing to lose. In contrast, those who have incorporated a well-integrated sense of self and commitments to a view of the self in the future are less likely to take these risks. In research focusing on specific health problems, such as diabetes or congenital heart disease, having a well-integrated identity and sense of purpose may operate to provide some protection against the anxieties associated with the disease and support commitment to the maintenance practices that help keep the disease under control (Schwartz et al., 2013).

Developmental Progression

The theoretical construct of identity status is built on the assumption that the process of exploring alternative roles and values, and making commitments requires a reconstruction of the self and associated strengthening of the ego. The identity statuses reflect different levels of both internal and external integration—an inner ability for self-reflection, review of alternatives, and hypothetical thinking about possible selves, and an external integration of the roles, expectations, and opportunities available in one's social and community contexts. Implied in this model is the assumption of a developmental progression where identity confusion is the least integrated status, movement from confusion to foreclosure and moratorium suggest greater ego strengths, and identity achievement reflects the most advanced status (Al-Owidha, Green, & Kroger, 2009; Kroger & Marcia, 2010). The following narrative illustrates the movement anticipated from moratorium to achieved identity:

> At the end of this summer, I left Canada for Scotland in order to pursue teaching education. This is something that I had planned on for a long time and was very sure about. I had been away from home before, but never as far away as another country. Although I only half completed the length of my time here, I have learned a great deal about myself that I didn't really see before. I have certainly proved that I am very independent. I had previously doubted this about myself. It felt rather fulfilling to feel such independence. I had the occasional doubt prior to coming here that it would be difficult, but little doubt exists in my mind now. (McLean & Pratt, 2006, p. 719)

Movement from achievement to one of the other statuses suggests regression. As a result of some destabilizing experiences, a person who has achieved identity at one period may conceivably return to a crisis period of moratorium or confusion. However, those who are in a moratorium or achieved status can never be accurately described as foreclosed, because by definition they have already experienced some degree of crisis (Meeus, 1996; Waterman, 1982). A number of cross-sectional and longitudinal studies have shown that over time, more young people have the mature identity statuses of moratorium and achievement, and fewer are in foreclosure or identity confusion (Kroger, Martinussen, & Marcia, 2010; Yip, Seaton, & Sellers, 2006).

In the process of evolving an individual identity, everyone experiences temporary periods of confusion and depression. The task of bringing together the many elements of one's experience into a coordinated, clear self-definition is difficult and time consuming. Most adolescents experience moments of self-preoccupation, isolation, and discouragement as the diverse pieces of their identity puzzle are shifted and reordered into the total picture. Thus, even the eventual attainment of positive identity formation will be the result of some degree of identity confusion. The negative outcome of identity confusion, however, suggests that the person is never able to formulate a satisfying identity that will provide for the convergence of multiple identifications, aspirations, and roles. Such individuals have persistent fears that they are losing their hold on themselves and on their future.

Identity Formation for Men and Women

Questions have been raised about whether the theory of identity formation, applies equally well to men and women. A summary of research comparing the course of identity development for males and females finds no evidence of gender differences in the timing or the process through which identity is formed (Coté, 2009). The kinds of ego strengths associated with identity achievement are equally important to the adaptive functioning of men and women. Men and women are equally likely to be distributed across the four identity statuses. Over the period of later adolescence, they show the same pattern of increasing frequencies in the moratorium and achievement categories and decreasing frequencies in the foreclosed and confused categories (Kroger, 2004).

Some have argued that the concept of identity as it has been formulated is a reflection of a male-oriented culture that focuses heavily on occupation and ideology rather than on interpersonal commitments as the foundation for identity content. These critics suggest that the construct of personal identity places greater value on self-sufficiency and autonomy, characteristics associated with the traditional male gender role, and less value on the building of close relationships and connections to the group, characteristics associated with the traditional female gender role (Archer, 1992; Sorrel & Montgomery, 2001).

Some evidence of gender differences has been found in the salience of various domains in the *content* of identity. Erikson's (1968, 1982) work suggested that ideological and vocational commitments are central to identity formation. Gilligan (1982/1993) criticized this orientation, arguing that interpersonal commitments may be more central for women and that its clarification opens the way for more advanced exploration of vocations and ideology. The early studies of identity status were conducted with male participants. As the approach gained traction, the interview method was modified to include domains that were thought to be especially relevant for young women, particularly ideas about relationships, sexuality, and family. These along with the focus on occupational and ideological commitments continue to be part of the assessment method for both men and women (Marcia et al., 1993). Research lends some support to this view. The quality of interpersonal relations and the establishment of satisfying social commitments are more central to the content of personal identity for women. Women are more likely to be in the identity achieved or moratorium status than men in relational domains such as family, friendship, or the values relating work and family (Kroger, 2002).

FURTHER REFLECTION: *Evaluate factors that may make it difficult for someone to resolve the crisis of individual identity versus identity confusion during the period from 18 to 24 in contemporary U.S. society. Think about the idea of identity status. What experiences might foster movement from moratorium status to achieved status? What experiences might destabilize identity, resulting in regression from achievement to moratorium?*

The Central Process: Role Experimentation

The concept of identity status, which has dominated the research on identity development, implies steps or levels of attainment in one's identity work. This approach may obscure the important question of how adolescents go about the task of figuring out their values and commitments. The central process of **role experimentation** suggests an answer to this question. Later adolescents experiment with roles that represent the many possibilities for their future identities. They may imagine themselves in a variety of careers in an effort to anticipate what it would be like to be members of specific occupational groups. They may take a variety of summer jobs, change their college major, read extensively, and daydream about success in several occupations. They consider whether to marry, and they begin to define the ideal qualities they are looking for in a long-term intimate partner. Dating is one form of role experimentation; it allows for a different self-presentation with each new date. Friendship is another important context within which young people begin to clarify their interpersonal commitments. Later adolescents may also evaluate their commitment to their religion, consider religious conversion, or experiment with different rationales for moral behavior. They may examine a variety of political theories, join groups that work for political causes, or campaign for candidates.

Some researchers have conceptualized the process of role experimentation as a cycling of commitment formation and commitment reevaluation (Klimstra et al., 2010). Early in the identity formation process, this cycle may occur frequently, possibly daily, as young people vacillate between certainty about their values or commitments and uncertainty about whether these commitments make sense. For example, as a freshman in college Sam tells his parents that he wants to major in political science and become a lawyer. Then, after a few weeks he tells his folks that he wants to go into the field of foreign service and be a diplomat. By the time Sam comes home for Thanksgiving, he is talking about getting more involved in the student government and thinks that when he graduates from college he would like to go into politics. By his senior year, Sam has changed his mind about his future career five or six times, but each time he comes back to his interest in the law and ends up applying to law school. Over time, as commitments become more stable, the young person will experience greater confidence and fewer episodes of reevaluation.

Psychosocial Moratorium

The process of role experimentation takes many forms. Erikson (1959) used the term **psychosocial moratorium** to describe a period of free experimentation before a final identity is achieved. Ideally, the moratorium allows individuals freedom from the daily expectations for role performance. Their experimentation with new roles, values, and belief systems results in a personal conception of how they can fit into society so as to maximize their personal strengths and gain positive recognition from the community. The idea of being able to disconnect from daily demands and experiment with new roles may be more difficult for some later adolescents than for others. For example, young people who marry early and who go into the labor force right after high school may not have the luxury of a moratorium.

The concept of the psychosocial moratorium has been partially incorporated into some college programs that permit students to enroll in pass–fail courses before they select a major. The intention is to eliminate the problems of external evaluation during the decision-making process. The concept of a "Gap Year" is gaining traction. After graduation, some high school students take a year off for a combination of work, travel, or volunteer service

Goodluz/Shutterstock.com

For some later adolescents, the psychosocial moratorium allows them to explore the wonders of nature and test the limits of their physical capabilities.

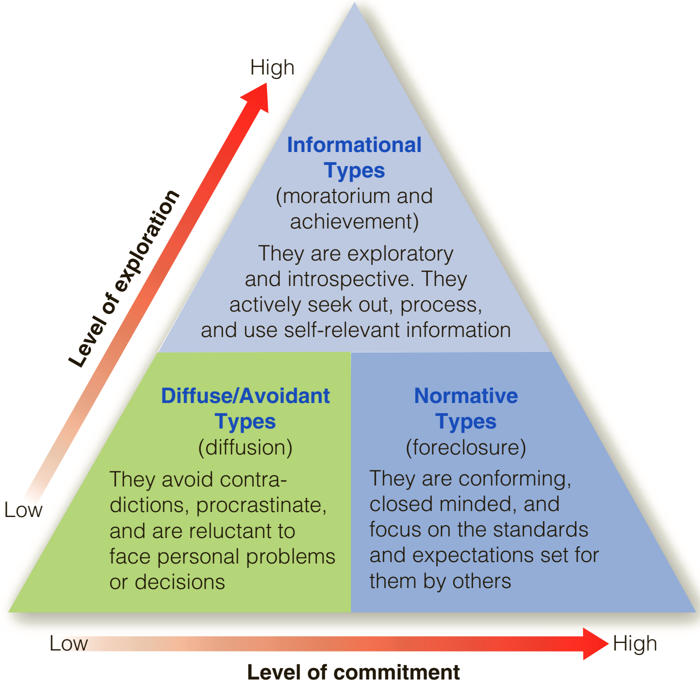
before deciding about college or career. Some colleges encourage students to take this year by offering a delayed admission (National Association for College Admission Counseling 2016; Ruiz, 2011). College students often express a need for a moratorium by leaving school for a while, disrupting the expected path of educational and career development. They assert their autonomy by imposing their own timetable and agenda on a socially prescribed sequence. Travel abroad is another strategy for experiencing moratorium. The time spent in another culture can give students an opportunity to demonstrate self-sufficiency, examine many of their assumptions about values and goals, express their individuality, and break out of whatever social environment they may feel is constraining or overshadowing their sense of self. The moratorium offers temporary relief from external demands and an opportunity to establish their identity.

As parents observe the process of role experimentation, they may become concerned because their adolescent son or daughter appears to lack direction or purpose. Parents are well advised to understand role experimentation as the expression of an appropriate developmental process in which a young person is trying on various roles, beliefs, and philosophies to see how they fit. If at all possible, parents need to trust in this process, giving their opinions and reactions when appropriate, but encouraging the young person to find the combination of roles, values, goals, and commitments that bring her the greatest feelings of enthusiasm and optimism about her own future.

Individual Differences in Role Experimentation

Not all young people approach the process of role experimentation with the same degree of openness to new experiences and new information. Michael Berzonsky (1989, 1993, 2011) hypothesized that in later adolescence, individuals differ in how they select, process, and apply self-relevant information. Three types of approaches to identity-related information processing were described. The *informational types* "actively seek out and evaluate self-diagnostic information when negotiating identity issues and making decisions" (Berzonsky, 1993, p. 289). The *normative types* are "relatively more defensive and closed to feedback that may threaten hard core areas of the self" (Berzonsky, 1993, p. 290). The *diffuse-avoidant types* "procrastinate and delay dealing with self-relevant issues as long as possible. When push comes to shove, they tend to be influenced by immediate rewards and operate in a situation-sensitive fashion" (Berzonsky, 1993, p. 290). The three identity-processing styles are associated with distinct patterns of defense mechanisms that come into play when later adolescents encounter conflicts or threats to their identity. The informational types use cognitive strategies to minimize anxiety. The diffuse-avoidant types use defenses that turn aggression inward toward the self or outward, blaming others. The normative types use mechanisms of denial, distortion, and negation to defend against threatening information (Berzonsky & Kinney, 2008).

An implication of this theory that the path toward identity status depends in part on how willing a young person is to engage in role experimentation. The informational types are most likely to initiate role experimentation as a means of clarifying existing beliefs and values. The normative types have to process contradictions among the demands and expectations of the varying roles they play, but if possible, they will probably avoid novel experiences that would challenge their views. The diffuse-avoidant types may engage in role experimentation if it is viewed as cool or is positively regarded among others in their peer group, but they probably would not take the initiative to seek out new experiences as a conscious, proactive strategy. FIGURE 10.6 ▶ shows the relationship between the three information-seeking styles and the four identity statuses described earlier. In this model, exploration or seeking information is associated with both the moratorium and the achieved statuses (White, Wampler, & Winn, 1998).



High
Level of exploration
Low
Informational Types
(moratorium and achievement)
They are exploratory and introspective. They actively seek out, process, and use self-relevant information
Diffuse/Avoidant Types
(diffusion)
They avoid contradictions, procrastinate, and are reluctant to face personal problems or decisions
Normative Types
(foreclosure)
They are conforming, closed minded, and focus on the standards and expectations set for them by others
Low
High
Level of commitment

FIGURE 10.6 ▶ RELATIONS AMONG IDENTITY STATUS, LEVEL OF EXPLORATION, AND LEVEL OF COMMITMENT

Source: White, Wampler, and Winn, 1998, p. 226.

Role experimentation implies an active process by which later adolescents sort through various identifications, scripts, and social pressures in order to clarify their commitments. For some young people, however, a **turning point** or critical incident marks the point of commitment. Often, a dramatic loss, an unexpected victory, or an experience of victimization can help crystallize a young person's vision of how the self can fit in with the community or transcend the community. For later adolescents who experience stressful life events, the experience of suffering, struggle for meaning, and coping may result in new levels of personal insight that support the identity process (Marcia, 2010; McLean & Pratt, 2006). Two examples of turning points are illustrated in the following case study.

— CASE STUDY Turning Points in the Identity Process —

The following two examples illustrate how a critical life event can refocus personal identity toward a new consolidation of energy, purpose, and commitment. In the first example, Sullivan experiences personal losses that lead to a new occupational and value commitment. In the second example, Rachel experiences a national tragedy that reorients her political ideology.

Sullivan

Sullivan was living with her mother in a housing project. In high school, when life got very hard, she began drinking and using drugs. She often stayed out late "to all hours" without her mother knowing or caring. Her father stepped in, put his foot down, and tried to teach her better habits. Soon after high school, she eloped with a young man who tried to control her and keep her from going to college.…The marriage ended after two years, then tragedy followed. An old boyfriend of Sullivan's committed suicide, and shortly thereafter her sister was hospitalized because of a suicide attempt.

The near-death of her sister changed Sullivan. She did not want to be a "loser"—someone who could not pull her weight—so she enrolled in a local community college. She went on to earn a bachelor's degree and then a master's degree, and she became a licensed social worker. Now Sullivan's work is aimed at helping people who are like she was. (Levine & Nidiffer, 1996, pp. 122–123)

Rachel

When I was 19, I moved to New York City to be a musician. The first thing I did was get a tattoo on each hand: One was a treble clef, the other was the insignia for Silvertone guitars.…

If you asked me to describe myself then, I would have told you I was a musician, a poet, an artist and, on a somewhat political level, a woman, a lesbian, and a Jew. Being an American wouldn't have made my list.

I'm a junior at a Manhattan college. In my Gender and Economics class earlier this semester we discussed the benefits of socialism, which provides for all members of society, versus capitalism, which values the self-interests of businesspeople. My girlfriend and I were so frustrated by inequality in America that we discussed moving to another country. On September 11, all that changed. I realized that I had been taking the freedoms I have here for granted. Now I have an American flag on my backpack, I cheer at the fighter jets as they pass overhead, and I am calling myself a patriot.

I had just stepped out of the shower when the first plane crashed into the North Tower of the World Trade Center. I stood looking out the window of my Brooklyn apartment, dumbfounded, as the second plane barreled into the South Tower. In that moment, the world as I had known it was redefined. (Newman, 2001, p. 9)

CASE ANALYSIS Using What You Know

1. Discuss the difference between turning points and role experimentation.
2. Examine the factors that might determine whether a turning point leads to identity achievement or identity confusion.
3. Contrast the events that Sullivan experienced and those that Rachel experienced. How might the differences in these two kinds of events relate to subsequent identity work?
4. Generate a list of factors that might be necessary to preserve the focus and sense of purpose that are evoked in these critical life events. For example, how might family support, the response of close friends, or opportunities for enacting new roles influence whether these changes are sustained?

Role Experimentation and Ethnic Identity

In chapter 9 (Early Adolescence), we introduced the idea that group identity precedes individual identity. One component of group identity is an orientation toward one's ethnic group. Efforts to understand one's **ethnic identity** and to clarify one's commitment to a particular ethnic subculture lead to self-definition that facilitates work on personal identity as well (Yip, Seaton, & Sellers, 2006). Part of forming a clear sense of personal identity may require an understanding of one's ancestry, especially one's cultural and ethnic heritage and the values, beliefs, and traditions that may have shaped one's childrearing environment as well as one's vision of the future. Ethnic group identity typically involves the incorporation of certain ideals, values, and beliefs that are specific to that ethnic group; a sense of how this ethnic group is regarded by outsiders; and the way in which one orients oneself with respect to this group—that is, whether one seeks out other members of the group, feels proud of one's membership in it, and has positive attitudes about it (Cross, 1991).

As you might imagine, young people make the transition from early to later adolescence having done different amounts of work in exploring their ethnic group identity. One theory of ethnic minority identity development offers a five-stage model (Atkinson, Morten, & Sue, 1983):

1. *Conformity*. Identification with the values, beliefs, and practices of the dominant culture.
2. *Dissonance*. Recognition and confusion about areas of conflict between the values, beliefs, and practices of the dominant culture and those of one's own ethnic group.

3. *Resistance and immersion*. Rejection of many elements of the dominant culture; education about and involvement in one's own ethnic group and its beliefs, values, and practices.
4. *Introspection*. Critical examination of the values, beliefs, and practices of both the dominant culture and one's own ethnic group's views.
5. *Articulation and awareness*. Identification of those values, beliefs, and practices from the dominant culture and from one's own ethnic group that are combined into a unique synthesis that forms a personal, cultural identity.

Exposure to the college curriculum offers an intellectual framework for understanding the historical, psychological, and sociological foundations of racism, prejudice, and cultural conflict (Phinney, 1996b). The complex interweaving of ethnic identity exploration, personal identity exploration, and the pursuit of academic goals results in a variety of individual trajectories (Syed, 2010). Over the period of later adolescence, young people gradually progress from an unexplored or unexamined ethnic identity to a more fully articulated understanding of how race and ethnicity contribute to their sense of self, and a stronger sense of ethnic group membership (Fuligni, Hughes, & Way, 2009). In one study of American Indian college students, the contribution of ethnic identity to well-being was examined. Those students who had a strong identification with their American Indian heritage and who socialized primarily with other American Indians were more likely to express feelings of historical loss. In contrast, the students who were more strongly assimilated into mainstream culture were less likely to struggle with these feelings (Tucker, Wingate, & O'Keefe, 2016). The implication of this research is that for some students, the formulation of a strong ethnic identity may increase one's sensitivity to the societal harms that have been inflicted on one's group.

This model highlights the interaction between ethnic identity and personal identity (Cross & Fhagen-Smith, 2001; Rotheram-Borus & Wyche, 1994). Not all young people experience all of these stages. Some children are raised in families where ethnic socialization begins at a young age, and they never experience a sense of tension between their ethnic background and that of other groups. If they are raised in an ethnically segregated community, they may not encounter members of other cultural or ethnic groups as significant figures during their early childhood years. For others, their family and community focus emphasizes religious affiliation or social standing over ethnic identity, placing relatively little emphasis on ethnicity as a defining aspect of the self.

But for many, later adolescence is the stage when exploration about ethnic identity is highlighted (see the **Human Development and Diversity** box Ethnic Identity and Adjustment). Ethnic identity exploration and commitment typically increase over the college years (Syed & Azmitia, 2009). Ethnic identity may become one lens through which students make decisions about their college major. As they participate in this major, they may experience new insights about the fit between their career aspirations and their social identity. The college environment also provides a social climate that may stimulate new ideas about ethnicity. Having attended an ethnically diverse high school, some students have already given thought to how their ethnicity fits in with their goals, career ambitions, and personal values. They may welcome opportunities to explore various cultural perspectives in coursework and student organizations. For others, arriving at college at the stage of conformity, the college environment brings a new awareness of conflicts that pervade contemporary culture. They may find that the student body is much more diverse than high school. Young people of many racial, ethnic, social-class, regional, and religious backgrounds come together in college and are expected to live together in the residence halls, learn together in the classrooms, and collaborate in college organizations, social activities, sports, and cultural events. Exposure to this diversity may be accompanied by experiences of racial and ethnic prejudice, cultural ethnocentrism, and intergroup conflict. The following example illustrates what some students encounter as aspects of a hostile or demeaning campus climate

> Alejandra Padin-Dujon, a sophomore who is an Afro-Latina, said her experience has ranged from being called

Jim Sugar/Corbis Documentary/Getty Images

The college environment provides an opportunity for students to learn about their cultural identities and the history of their ethnic groups.

HUMAN DEVELOPMENT AND DIVERSITY

Ethnic Identity and Adjustment

Ethnic identity has been studied as a component of the self-concept, usually focusing on how important people's ethnicity is to them, how often they think about themselves as members of their ethnic group, and how close they feel to other members of their ethnic group (Sears, Fu, Henry, & Bui, 2003). Ethnic identity has also been measured as a general concept, allowing one to compare the strength of ethnic identity across groups. The *Multigroup Ethnic Identity Measure* (MEIM) is one such measure, which consists of two subscales (Phinney, 1992; Roberts et al., 1999):

1. *Affirmation, belonging, and commitment*, which assesses one's feelings of connection and pride in membership.
2. *Ethnic identity search*, a developmental and cognitive component, which assesses a person's efforts to be involved in activities and practices associated with their ethnic group and to increase their understanding of the group and its history and traditions.

The MEIM allows one to characterize individuals along a continuum from an unexamined ethnic identity acquired with little exploration or commitment (*low ethnic identity*) to a well-developed, achieved ethnic identity (Yasui, Dorham, & Dishion, 2004). The parallels with personal identity status are striking, capturing the two processes of exploration (crisis) and commitment.

Ethnic identity, as measured by the MEIM, has been positively associated with self-esteem across middle childhood, early adolescence, and later adolescence. Individuals with positive ethnic identity deal more effectively with threatening social situations involving discrimination and stereotyping (Roberts et al., 1999). A sense of belonging to one's ethnic group may be important as part of one's social identity for all groups. However, the *salience* of ethnic identity is not the same for all groups. The establishment of a clear acceptance of their ethnic identity may be especially relevant for those who face discrimination or oppression on the basis of their ethnic membership.

A growing group of later adolescents identify themselves as multiracial or biracial. One estimate finds that close to 7 percent of Americans are multiracial and with the increase in multiracial marriages, this group is likely to grow (Pew Social Trends, 2015). However, many people with a multiracial heritage do not consider themselves multiracial. Others reject the traditional categories of race and ethnicity in favor of a more nuanced acceptance of diverse backgrounds and ancestries (Ojalvo, 2011). Having spent time figuring out how they fit into their families and communities, they come to later adolescence with a greater openness toward other groups and heightened appreciation for the value of cultural diversity.

> I am Italian and African American and I am proud of all my heritages. My origins are diverse, but so is the world around me. I grew up in a national forest reserve which lent me a respect for rural America. Growing up I worked as a Thai sous chef for a Thai immigrant. He taught me to cook and I developed that skill in college where my primary supermarket in college became Patel's Cash and Carry. Two of my best friends are Muslim by way Bangladesh, but dress like 1930's French models. One is Polish and Irish who loves her Peruvian gay uncle. The love of my life is a first generation Cuban-American who works for a major East Asian Research Center. I am happy to consider myself uniquely American. I could have only happened here. (Ojalvo, 2011)

Critical Thinking Questions

1. Evaluate how well the two scales from the MEIM, ethnic identity search and affirmation, belonging, and commitment, capture the meaning of ethnic identity. What other dimensions would you add if you were going to modify this measure?
2. Describe the parallels between ethnic identity and personal identity. How might they relate to each other as the person matures? Can you imagine having an achieved personal identity without a clear ethnic identity? What about vice versa?
3. Summarize the personal, family, and community factors that might determine how important or salient ethnic identity is for an individual or for an ethnic group.
4. Predict how the increasing number of multiethnic youth may alter the way we think about and study ethnic identity in human development.

> a "racial epithet" as a "joke" to what she sees as more subtle forms of racism: an advanced physics professor who suggested she might be better off in an easier class; students who suggested in various ways that she's at Yale because of affirmative action; and well-meaning friends who suggested that she would look prettier if she straightened her hair. (Megan, 2016)

At the same time, encounters with ethnic diversity may contribute to more divergent thinking, new perspectives about beliefs and values, and, as a result, more complex thinking about social issues (Antonio et al., 2004; Syed, 2010).

The Prime Adaptive Ego Quality and the Core Pathology

In the process of resolving the crisis of identity versus identity confusion, later adolescents have to examine their values and goals. This process relies upon more advanced executive functioning, including the capacity to take a step back from one's current commitments and reflect on their meaning as well as an ability to deliberately seek out new sources of information and ideas that can inform personal decisions (Klimstra et al., 2010). As a result of this reflective work, later adolescents who achieve a sense of personal identity are also likely to benefit from a clearer, more confident sense of their values and beliefs. In contrast, later adolescents who experience identity confusion are likely to leave this stage of life with the core pathology of repudiation—a rejection or standing *against* rather than standing *for* specific beliefs and values.

Fidelity to Values and Ideologies

Fidelity to values and ideologies is closely linked with the notion of *commitment*. In later adolescence, the ego strength of **fidelity** refers to "the ability to sustain loyalties freely pledged in spite of the inevitable contradictions and confusions of value systems" (Erikson, 1978, p. 28). Fidelity incorporates the trust and hope of infancy and directs it toward a belief in values and ideologies. Fidelity may be fostered by identification with inspirational role models or by participation in meaningful institutions. It is also achieved as a result of the new cognitive capacities of adolescence that permit self-reflection, relativistic thinking, and insight. Fidelity to values and ideals provides evidence of a reflective person who has taken time to struggle with opposing views and to select those that best reflect personal convictions (Waterman, 1992).

The emergence of fidelity to values provides a channel for guiding strong passions and drives toward the achievement of meaningful goals. At the close of later adolescence, young people who articulate specific values and goals, such as making a contribution to their community, gaining new levels of expertise in their chosen field, or establishing a loving, caring relationship, are more likely to experience a sense of subjective well-being in the years ahead as they take deliberate steps toward goal attainment (Bauer & McAdams, 2010). Fidelity to values strengthens one's ethical resolve, especially in the face of the many pressures and temptations of adult life. It also creates a bond of belonging with others who share the same loyalties. At the same time, fidelity in the individual strengthens the society by drawing on the commitments of those who share a common set of values to sustain and support basic institutions, such as religious organizations, political parties, educational institutions, and social service agencies.

Fidelity to values and ideologies is closely linked to the developmental tasks of autonomy, gender identity, moral development, and career choice. In each of these domains, the young person faces challenges that may undermine self-respect, or that may foster in-group favoritism over out-group derogation. When individuals perceive their own personal or group identity to be threatened, they are more likely to withdraw, lash out, or reject the values of others. When individuals perceive a context of acceptance, inclusion, and fair treatment, they are more likely to be open to dialogue and cooperation. We do not know which values a young person will embrace. However, the more individuals are treated in a humane, respectful, and inclusive manner, the greater the likelihood that these values will be reflected in their outlook toward others (Andersen, Downey, & Tyler, 2005).

Repudiation

Repudiation refers to a rejection of certain values, beliefs, and roles. In the diverse and pluralistic society of the United States, some degree of repudiation may be necessary in order to forge an integrated identity. One cannot embrace all ideologies and roles; each commitment brings some boundaries to one's values and limits one's investment to a certain vision of the self as continuing into the future. Repudiation can serve as a mechanism for intergenerational change. For example, a young person may decide that he will reject the characteristics of an unloving or abusive parent or a bigoted political figure. In this context, the young person will form an identity around suppressing certain negative qualities and learning to enact and endorse opposing positive qualities.

In the extreme case, repudiation results in a hostile rejection of all the ideas, values, and groups that do not adhere to one's own beliefs (Erikson, 1982). It fosters a rigid worldview that does not admit to the contributions of others' ideas. The roots of militancy, prejudice, and terrorism lie in the formation of the core pathology of repudiation. Imagine young people who, on the threshold of adulthood, see their future as grim or hopeless. They may perceive themselves as subjugated victims, rejected by the mainstream. They may believe that their culture, their ethnic identity, or their religion is mocked or berated. The energy of youth that can mobilize noble, courageous acts of fidelity can also crystallize around hate, turning against one or more groups in acts of violence.

Applied Topic: Dropping Out of College

OBJECTIVE 6 Examine some of the predictors and consequences of dropping out of college and hypothesize how dropping out of college may influence development in later adolescence.

A sizeable percentage of students who enroll in colleges leave without a degree. In general, the percentage of the U.S. population with advanced degrees has not grown much over the past 10 years. Among those ages 25 to 34, about 36 percent have a bachelor's or advanced graduate or professional degree (Ryan & Bauman, 2016). Although the majority of high school graduates (68 percent in 2014) attend some type of postsecondary institution in the year following high school, many do not graduate. The national graduation rate for students who enrolled full time at 4-year colleges and universities was 59 percent after 6 years. These rates differ by state, type of institution (public or private, research university or liberal arts college), and by students' race/ethnicity and family economic resources. Degree completion is notably lower for students entering college whose families have limited economic resources and for certain ethnic minorities, who tend to be overrepresented among low-income families (Kena et al., 2016). This picture is incomplete because the federal government does not track part-time students or those who enroll in one college and graduate from another.

Models of student retention and persistence suggest that degree completion is a result of the interaction of four classes of factors: financial factors, academic preparation, personal factors, and characteristics of the college environment (Newman & Newman, 1999).

Financial Factors

The cost of tuition, room, board, and fees increased 67 percent at public universities and 43 percent at private universities (in 2015 dollars) from the 2000–2001 academic year to the 2015–2016 academic year (College Board, 2016). These increases far outpaced the average increase in family income over the same period. Among college freshmen, about two thirds state that they are either somewhat or very concerned about their ability to finance their college education (Eagan et al., 2015).

It is no surprise that college students in the lowest quartile of family income are less likely to graduate than those in the higher quartiles. Students from poor families are more likely to be working several jobs to pay for school. Often they are troubled by the burden of growing debt and are uncomfortable about borrowing more. Many students have financial responsibilities for their family members. In some cases, they send some of their scholarship money or income from part-time work home to help support their family. Unexpected fees, and textbook and laboratory costs associated with college courses, are more difficult to cover for students from poor families because they have less access to supplemental financial resources. These students' parents have fewer resources and cannot help them meet unanticipated expenses. Students who dedicate their summer earnings to paying for tuition and fees do not have enough discretionary income to cover unanticipated costs.

In order to manage the financial requirements of attending college, many students make a combination of decisions that put them at risk for **dropping out of college**. They decide to save money by living at home, and they work more hours a week at jobs to help defray expenses. Both of these factors, living off campus and working long hours, are associated with an increased likelihood of dropping out of college (Bozick, 2007). Because they are not living on campus, they are less likely to feel a part of the college community and less likely to benefit from the friendship and social and academic support of other students. Working 20 hours or more per week makes it just about impossible to become involved with campus activities that might increase feelings of belonging or to take advantage of campus services and resources about how to cope with the academic and career preparation demands of college. When demands from classes conflict with demands from work, students from low-income families are less likely to be able to cut back on work hours.

In many cases, students from low-income families have had to establish independent financial status and do not receive any funds from parents. These students may also have attended high schools that did not provide adequate academic preparation, resulting in a requirement to take additional developmental coursework that does not count toward a college degree (Stinebrickner & Stinebrickner, 2008). Over time, students who are working at a job many hours a week just to keep up with tuition payments may find that life in college is more stressful and less enjoyable than it seems to be worth.

Academic Preparation

The following factors that precede college enrollment have all been found to relate to college retention and graduation:

- Attendance at a college-oriented high school
- Participation in a college-preparatory curriculum
- Parents' educational background
- Family's educational values and goals
- The student's intention to attend college
- Clarity of career goals
- High school coursework and grades

A rigorous high school curriculum is the strongest predictor of postsecondary persistence and success (Adelman, 2006). Students with inadequate academic preparation and lack of familiarity with the college environment are more likely to leave before graduating. High schools in low-resource neighborhoods are less likely to offer the rigorous curriculum that best prepares students for academic achievement in college.

There is growing concern among college faculty that students are not prepared to meet their expectations for writing, mathematics, independent work, critical thinking, detailed examination of information, and complex problem solving (Sanoff, 2006). Early failure experiences in college courses can result in a decision to drop out of college. Michael Van Adams' story illustrates this process:

> Van Adams . . . told himself that the University of Maine wasn't for him. He dropped out a couple of weeks before completing his first semester. "Frankly, I wasn't properly prepared for college," he says. "I didn't go into my freshman year with the right attitude. At age 18, I thought I had the world figured out; I thought I could ace my college classes like in high school. I couldn't have been more off. I was failing three classes, and I didn't see the point of sticking around." (Whitbourne, 2002)

Students may have an unrealistic idea about their academic preparation for college. A survey of college freshmen in 2015 found that over 70 percent rated their academic ability as in the top 10 percent or above average (Eagan et al., 2015). However, when they arrive in college, they discover that the combination of their academic preparation and their study skills are inadequate for the new demands of college-level courses. College mathematics and science courses are prerequisites for many majors. Students who fail an early mathematics or science course may realize that they will not be admitted to the major of their choice and decide to leave school. Students who have been accustomed to ranking in the top 10 percent of their high school class may be shocked to receive grades of C or D in college courses. They may assume that they do not have the ability to do college work. When students receive bad grades, especially when they expected to do well, they may begin to view college as less enjoyable and more stressful than they had hoped, leading to a decision to drop out (Stinebrickner & Stinebrickner, 2012). Many colleges have cut back on offering pre-collegiate or developmental courses in writing, mathematics, and science, thereby removing the support for students whose high school curriculum did not prepare them adequately for college-level work.

Personal Factors

The theme of personal identity and its salience in later adolescence is central to the decision to remain in college or leave. For many students, the decision to go to college is a commitment to a view of oneself in the future as a person who is more accomplished,

Ute Grabowsky/photothek images UG/Alamy Stock Photo

Michelle is packing up her room. She is glad to be leaving; after two semesters she realized that college was just not for her.

prepared to function at a higher level, earning a better income, and being in a better position to direct the course of one's life. Students who have a clearly defined goal and strong motivation to persist are more likely to stay in college and graduate (Morrow & Ackerman, 2012). Within the college environment, identity work can be fostered as one is supported by others who validate the sense of a future self that is taking shape. It can be reassuring to be encouraged by family members and surrounded by peers who have similar academic aspirations. Interacting and identifying with faculty and graduate students who are pursuing interests as models for the future, the young person begins to see how personal goals may be attained (Kelly, LaVergne, Boone, & Boone, 2012). College coursework and interactions with peers can result in growth in worldview and exposure to new models of organizing, analyzing, and representing experience.

A variety of personal factors can interfere with this process. Once in college, the level of a student's social and academic integration, along with the wavering intention to complete college, can affect decisions to stay in school. Reflecting back on their first year in college, some students say they were not really sure why they enrolled. Going to college was the norm in their high school, or an expectation from their family (Hanford, 2013). They arrived at college without any clear idea about what they hoped to accomplish. Personal factors that can contribute to dropping out of college may include:

- Lack of a clear idea about one's interests; no sense of purpose
- An inability to cope with the new demands for autonomy, time management, and competition
- Disillusionment with the environment of college
- Discouragement or confusion about one's ability to achieve important goals
- The onset of mental health problems
- Alcohol or drug abuse/use
- Victimization

The college environment presents new challenges to mental health. Many students suffer from mental health problems that were managed satisfactorily in high school, but that become more challenging in the college environment. Away from family, friends, and familiar medical resources, students may stop taking their medication, become overwhelmed by anxiety or depression, or engage in new risky behaviors that impede their ability to concentrate. Being away from home may result in unexpected feelings of loneliness and isolation. The college environment typically introduces new opportunities to make decisions about daily life, and, as a result, brings new demands for time management. Students may feel unable to succeed at the academic or social demands of the environment. They may feel overwhelmed by the number of tasks or the social stimulation. Students who are participating in competitive athletics may have difficulty meeting expectations to perform at a new, high level. Feelings of being overwhelmed or overloaded may result in poor academic performance or low levels of life satisfaction that can lead to dropping out of school (Larson, 2006).

The college environment also poses new challenges for students with disabilities. As students with disabilities make the transition from a structured and guided educational support process in high school to the post-secondary environment, the importance of self-advocacy increases. However, many college students do not engage in even the most fundamental forms of self-advocacy such as registering with a disability services office and requesting accommodations. One national study found that although 87 percent of the sample had received accommodations in high school, only 19 percent reported receiving accommodations at their postsecondary institution (Newman et al., 2011). A combination of factors, including meeting the academic demands of the student role, learning and enacting self-advocacy skills, and forming meaningful relationships can all be particularly challenging for students with disabilities, leading to higher rates of dropping out. Eight years after high school, fewer students with disabilities who began college graduated within this time frame (41 percent) in comparison to the general population (52 percent). For students attending 4-year colleges and universities, the rate of completion for students with disabilities was even lower, with 34 percent graduating within the 8-year time frame (Murray, Lombardi, & Kosty, 2014; Newman et al., 2011).

African American and Hispanic American students leave college at a higher rate than European American students, even when controlling for family income. This pattern is often attributed to a lack of a sense of connection or belonging in the college environment. Students who are doing well academically may decide to leave an environment where they are alienated, targets of discrimination, or disconnected from faculty and students (Walton & Cohen, 2011).

Characteristics of the College Environment

Characteristics of the college environment have also been associated with student retention. In a study of student retention at colleges and universities with large numbers of low-income students, the Pell Foundation compared schools with higher than average and lower than average graduation rates (Muraskin & Lee, 2004). School structure was associated with graduation rates. Universities characterized as Research I, where there were more graduate students and a greater emphasis on faculty research, had higher retention and graduation rates than the bachelor's degree/specialized colleges. Those institutions with higher graduation rates had more full-time students, a larger student enrollment, and more graduate students. These schools enrolled more students from the top half of their high school graduating classes. They had more full-time faculty, lower student/faculty ratios, and smaller classes. As a related factor, they spent more money per student full-time equivalent (FTE), and tuition and fees were higher, but these colleges were able to offset these costs with more grants to students.

Beyond these structural features, colleges and universities that were successful in graduating their low-income students focused on five aspects of the college environment (Muraskin & Lee, 2004):

- Building academic skills
- Providing financial support
- Working with students to help them clarify their academic direction
- Fostering a personalized environment for instruction and academic support
- Encouraging campus participation

Colleges that spend more money on student services have a lower dropout rate (Chen, 2012). At the colleges that are successful in graduating relatively large numbers of low-income students, one is likely to find pre-college or pre-enrollment courses to prepare students for the tone and tempo of college courses; supplemental services such as focused, proactive academic advising, study groups, and writing centers; and special housing groups, affinity groups, and interest groups to support students of common interest or background. Many of these campuses offer undergraduates research experiences with encouragement to consider graduate school. They create learning communities and organize students into social and academic groups in order to create a more personalized educational environment. These institutions express their commitment to retention and graduation through the ways faculty and staff interact with students, the care that is taken to create a supportive environment, and the encouragement that students experience to achieve their goals.

The Consequences of Dropping Out of College

In comparison to the research that has been done to predict student retention, relatively little is known about how students who drop out of college cope with this disrupted educational trajectory and its impact on their transition into adulthood. Dropping out of college does not necessarily solve the young person's problems and may introduce new ones. Abandoning the set of goals and activities that are linked to college attendance leaves the student in a directional vacuum. Formulating another set of goals and becoming involved in the activities required to achieve these goals may be difficult. There may be new pressures on the college dropout as people ask, "What are you going to do now?" While enrolled in college, students can cover some of their uncertainty by saying, "I'm in college." Dropping out means losing this protective, if somewhat ambiguous, role. This decision brings a need to recalculate and reorganize one's trajectory for the transition into adulthood. This task may be difficult and confusing because the identity work needed to flourish outside of college is different than the identity work required of the college student.

Dropping out has an impact on short-and long-term earnings. Leaving college has significant financial implications that will impact the young person's autonomy and capacity for financial self-sufficiency. As presented earlier in Table 10.1, the median income for a person who has some college but no degree is only slightly more than for a person who has graduated from high school. This difference in earning capacity increases as people move into their middle adulthood because opportunities for advancement are associated with higher levels of education. Moreover, those who attend college for a year or two and then leave are likely to have debts from tuition, fees, and other costs that they carry with them without hope of the increase in salary that might help them repay those debts.

Reduced educational attainment will have an impact on occupation. This in turn may have consequences for one's social status in the community. Dropping out of college may be accompanied by the loss of a peer group and the need to create a new social network and the possibility of disappointing family members. The lack of a college degree may make one a less desirable life partner and reduce one's marriage prospects.

Given the flexibility of the higher education system in the United States, there are many opportunities to reengage the college environment, including online enrollment, part-time status, evening and weekend courses, and continuing education. We do not know much about the process through which later adolescents who leave college without a degree decide to return or how they make meaning of their disrupted college years. Does the decision to leave college result in feelings of regret about unrealized promise? Or does the decision result in the formulation of a more authentic set of life goals that can be achieved without benefit of a college education? Perhaps this depends on whether the person views the decision to leave as an expression of agency or as evidence of failure.

There are many instances of people who do not graduate from high school or college, but who become engaged in creative, productive lives. A number of successful actors, singers, models, athletes, inventors, entrepreneurs, and authors have taken the non-collegiate route, choosing to use these years to become clearer about their life goals and to develop their talents (collegedropoutshalloffame.com, 2016).

FURTHER REFLECTION: *Summarize the reasons that someone might drop out of college. Link each reason to possible consequences.*

Examine the links between the developmental tasks of later adolescence and the decision to drop out of college.

Imagine that you are working as a residence hall advisor. What information from this chapter could you use to help counsel a student who is thinking of dropping out of school?

Analyze the possible positive and negative impact of this decision for career development, identity development, and psychosocial maturity.

CHAPTER SUMMARY

At the close of later adolescence, most young people are making the transition from childhood to adulthood. However, the process is gradual for most and increasingly prolonged into the decades of the 20s and 30s.

OBJECTIVE 1 Explain the concept of autonomy from parents and examine the conditions under which autonomy is likely to be achieved.

Later adolescents are striving for self-sufficiency in a complex culture. Many have achieved a new degree of independence from their parents, so that ties of love, trust, and support are expressed within a framework of mutual respect and autonomous decision making. Three components of achieving autonomy from parents are discussed: leaving home, attending college, and self-sufficiency. Families and cultural groups differ in their expectations about the nature of ties to parents in young adulthood, the timing of home-leaving, and the contexts in which support for autonomy is or is not provided. In the college population, students differ in their desire and readiness to loosen ties with parents, and parents differ in the encouragement and support they provide for independent decision-making. The process of achieving autonomy from parents opens the door to new considerations of basic ego structures, including gender identity, morality, and career aspirations. In each of these areas, a young person has the cognitive ability to reflect on the earlier socialization pressures of family and neighborhood and to construct a personal point of view.

OBJECTIVE 2 Summarize the development of gender identity in later adolescence. Analyze how the components of gender-role identification that were relevant during the early-school-age period are revised and expanded.

The formulation of gender identity requires an integration of the biological, psychological, and societal meanings associated with being a man or a woman. During later adolescence, young men and women formulate their gender identities as they encounter diverse and sometimes competing social messages, role relationships, sexual motives and activities, and dyadic interactions. These gender identities are situated in interpersonal, institutional, and cultural contexts. The components of gender identification that were established in early childhood are revised and reevaluated. New considerations are given to the ideas of gender constancy, gender role norms, and gender identifications. A sexual dimension is added to one's gender identity. These changes are taking place in the context of changing societal/historical conditions that have implications for how women and men are viewed and treated. Gender identity is a powerful lens through which many other aspects of personal identity are interpreted, including the content of values, commitment to family relationships, preferences and expectations for career choice, and beliefs about one's role in an intimate relationship.

OBJECTIVE 3 Investigate the maturation of morality in later adolescence, with special focus on the role of new cognitive capacities that influence moral judgments and the various value orientations that underlie moral reasoning.

Exposure to a diversity of information, relationships, and worldviews stimulates moral reasoning. The idea of an internalized morality is discussed as moral reasoning matures through progressive stages. Criticisms of Kohlberg's theory of moral reasoning are reviewed. Of particular interest is the focus on prosocial and caring aspects of morality. The concept of a maturing moral identity is discussed, including the expression of moral identity through a sense of purpose, civic engagement, and activism. The change from conventional to post-conventional morality that often occurs during later adolescence involves a rethinking of traditional moral principles. During this period, there may be a loosening of ties to the family of origin and an increase in encounters with an expanding network of friends, students, and coworkers. Through interactions with diverse reference groups, there is an increasing recognition of the cultural relativity of one's moral code. There may also be a degree of conflict over which moral values have personal meaning.

OBJECTIVE 4 Trace the process of career choice, with attention to education and gender-role socialization as two major influential factors.

The process of career choice, often accompanied by periods of uncertainty and confusion, is influenced by interacting factors, including personal abilities and attributes, emotional and motivational factors, family and societal factors, educational background, gender identity and gender-role socialization, and the situational realities of the current labor market. The work experiences of early adolescence are considered as a stepping stone in the career decision-making process. Three factors that influence career choice are reviewed: family context, education, and gender role socialization. A model of career decision making is presented that highlights the interaction of a maturing personal identity and a growing awareness of occupational opportunities and demands. Career decision-making self-efficacy is a concept used in the vocational development field to suggest that individuals differ in their confidence about making a sound decision. The role of the labor market and the changing nature of the world of work are discussed as they impact career decision-making. Ideally, one's choice of occupation is the result of personal experimentation, introspection, self-evaluation, fact finding, and intuition. As such, this choice becomes intimately interwoven with one's psychological development.

OBJECTIVE 5 Define and describe the psychosocial crisis of later adolescence, individual identity versus identity confusion; the central process through which this crisis is resolved, role experimentation; the prime adaptive ego quality of fidelity to values and ideals; and the core pathology of repudiation.

Those who have resolved the psychosocial crisis of individual identity versus identity confusion in the direction of identity achievement have an integrated identity that includes a definition of themselves as sexual, moral, political, and career participants. The sense of identity has both a public and a private face. It includes both content and evaluation suggesting that individuals may differ in the focus of their commitments to various aspects of work, family, ideology, and political life. The idea of identity status is explored, focusing on the two processes: crisis or exploration, and commitment. The four statuses that have received primary attention are: identity confusion, foreclosure, moratorium, and achievement.

The strain of this stage is felt in the tension between the person's need to question and experiment and the society's expectations for closure on significant themes, particularly occupation, gender identity, and political ideology. The expansion of roles and relationships exposes many young people to new views that require evaluation. The crisis of individual identity versus identity confusion suggests a new synthesis of earlier identifications, present values, and future goals into a consistent self-concept. This unity of self is achieved only after a period of uncertainty and open questioning. Role experimentation during this time is an essential strategy for coping with new information and new value orientations. Differences in how later adolescents approach the process of experimentation are reviewed. Once young people know what they stand for, they can commit themselves more deeply to others.

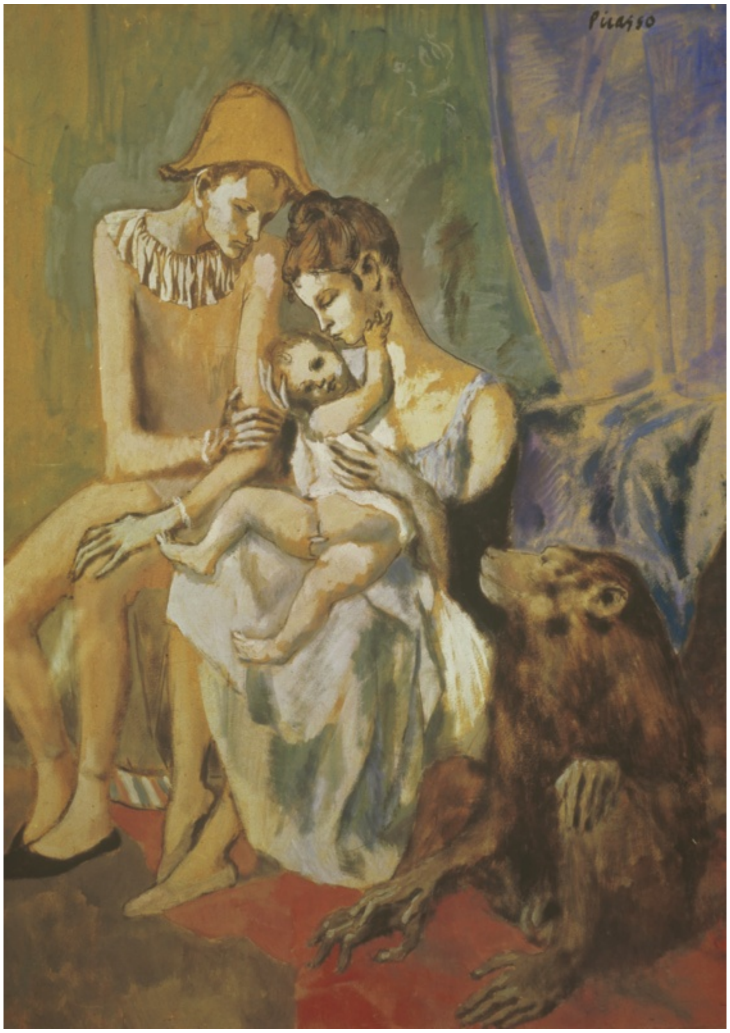
The prime adaptive ego quality of fidelity reflects the capacity to commit oneself to an ideology or belief system. The core pathology of repudiation suggests an intense rejection of certain values and beliefs. Although most later adolescents are forming a positive vision of the self that is connected to a shared community, some are defining themselves in opposition, as rebels, terrorists, or avengers.

OBJECTIVE 6 Examine some of the predictors and consequences of dropping out of college and hypothesize how dropping out of college may influence development in later adolescence.

The applied topic, dropping out of college, illustrates the fluidity of this period. Identity work, which requires an integration of one's biological, psychological, and social selves, takes place in concrete settings where daily demands and expectations must be met. Societal expectations set many young people on a path toward college that they cannot follow, whether for financial, academic, personal, or situational reasons. Colleges differ in their ability to foster a sense of belonging among diverse groups of students, as well as their readiness to provide academic, health, and mental health resources. The psychosocial consequences of dropping out of college are varied as reflected in individual accounts and narratives. The disruption of this academic trajectory poses significant challenges for establishing a life structure into adulthood. At the same time, it may invite more serious and considered reflection about what a person wants out of life and the activities and resources that will be required to achieve those goals.

CASEBOOK

For additional case material related to this chapter, see the case entitled "Life Turning Points and Career Choice," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 153–156. The case illustrates how a young person's encounter with a difficult personal situation leads to a revised sense of self and a new focus on meaningful goals for the future.



Bridgeman Art Library/Bridgeman Art Library/Superstock

The major themes of early adulthood—work, intimacy, marriage, and parenting—are all captured in this image of the young Harlequin family. We sense the vulnerability of a young family trying to create a life of love and tenderness in a difficult world.

LEARNING OBJECTIVES

1. Define and explain selected theoretical concepts that are especially relevant for understanding development during adulthood, including social roles, the life course, and fulfillment theories.
2. Analyze the process of forming intimate relationships, including initial attractions, mate selection, and commitment to a long-term relationship. Contrast the ways that different patterns of cohabitation contribute to the formation of close relationships. Summarize the challenges one faces in adjusting to the early years of marriage.
3. Describe the factors associated with the decision to have children, and evaluate the impact of childbearing on intimate relationships.
4. Define the concept of work in early adulthood and explore how work stimulates psychosocial development.
5. Examine the role of lifestyle development as an expression of an individual's personal identity, with consideration for the pace of life, balancing competing role demands, building a supportive social network, and adopting practices to promote health, fitness, and nutrition.
6. Define and describe the psychosocial crisis of intimacy versus isolation, the central process through which the crisis is resolved, mutuality among peers, the prime adaptive ego quality of love, and the core pathology of exclusivity.
7. Investigate divorce as a life stressor in early adulthood, including the factors contributing to it and the process of coping with it.

Chapter Summary

— **CASE STUDY** Changing Work to Recapture Love and Happiness —

A young man reflects on the delights of being in love, the disappointments of early career, and the decision to make a change.

In the course of our courting, there were frisbees-a-flying, beers-a-flowing, big bad barbeques, and more than a smattering of smooching and cuddles. Being together was easy and always.

We married in 1997, healthy, happy, and excited about our lives. All that we wanted was to be together and continue the fun and goofiness that attracted us to each other in the first place. Simple enough, seeing that we were getting married and all, right?

Change from 1998–2007 included such delights as increased pant sizes, long work hours, more doctor visits, decreased intimacy, a slump in the fun fund, fewer hours together, lack of peaceful sleep, lack of creative endeavors, and an increase in mindless spending, just to name a few.

What the hell happened during this nine year black hole of productivity, progress, and pleasure? Work happened. Two crappy jobs that we allowed to suck the life right out of us.

Fun, where ever did you go?

Mornings were filled with sullen grunts, brooding silences, sick heads and stomachs, and occasional weeping. Yes, even that. Evenings were a noxious mixture of prickliness and anxiety with the additional strain of trying to show love in the absence of the resources to make it so. The night was all tossing and turning with our minds running and repeating disturbing scenarios of the following day despite total exhaustion.

Finally, we admitted that we were very unhappy apart from each other, so we quit and opened our own guitar and tutoring studio.

Sullen morning grunts became laughter and five mile walks. The death defying and lonely commute became an animated discussion or business meeting on the way to the studio. Our commute now enjoyed together. Incompetent coworkers became employees of the month – every month. We really did hang an award on the wall of the studio too. Work hours got slashed by 50%. Evenings became filled with conversation, reading, and excitement over our tasty vittles. I can feel the excitement over the changes even now as I write and relive the lifting of the immense burdens of the past! Before we sleep, there is usually one more fit of giggles about some asinine thing we said or did. And night time now was filled with blissful, peaceful, complete, high-quality sleep – oblivion.

We wanted and got our time together back. And now that we have it, we clench it in our jaws like a rabid Tasmanian devil with a chip on its striped shoulder. And fun has returned screaming with vengeance.

CASE ANALYSIS Using What You Know

1. Discuss how concepts from social role theory are illustrated in this case. What are the key roles that a person is likely to enact in early adulthood? How might these roles enhance each other? Conflict with each other?
2. What are the sources of happiness and fulfillment that are central to this case? Describe some possible consequences of getting drawn into a work role that does not promote fulfillment.
3. Think about the period of early adulthood as a time for establishing a lifestyle that is in harmony with the goals, values, and commitments that were formed in later adolescence. Analyze how the case illustrates this idea. What are some reasons that young adults might experience uncertainty and a need to change? Evaluate the costs and benefits of making major lifestyle changes during this stage.
4. Speculate about the characteristics of the couple that will be central to their ability to weather their lifestyle change and support their marital satisfaction as well as their occupational well-being.

Welcome to the study of adulthood. All that has gone before can be seen as preparation; all that follows can be viewed as actualization. We have considered psychosocial development through seven preparatory stages of life, encompassing approximately 24 years. During these stages, an individual undergoes rapid physical, cognitive, social, and emotional development. In the United States, life expectancy at birth is currently about 79 years. Thus, 55 years or more remain after the seven preparatory stages. In our conceptual scheme, four stages of psychosocial development unfold during these 55 years. In this chapter, we discuss a few theoretical concepts that help account for the direction of development in adulthood. Then we address the developmental tasks and psychosocial crisis of the stage of early adulthood.

Expanding Theoretical Views of Adult Development

OBJECTIVE 1 Define and explain selected theoretical concepts that are especially relevant for understanding development during adulthood, including social roles, the life course, and fulfillment theories.

In chapter 2 (Major Theories for Understanding Human Development) and chapter 3 (Psychosocial Theory) we introduced a variety of theoretical concepts that explain the processes of continuity and change over the life span. In this chapter, we expand the discussion of theoretical constructs that help account for the directions of growth in adult life. The biological, psychological, and societal systems continue to interact, but the nature of lives becomes increasingly diverse and more difficult to characterize as stage-like over time. Life stories are guided by historical events, unexpected crises and opportunities, and personal choices. New levels of mastery, autonomy, and agency allow individuals to make decisions and choices about the kinds of environments in which they participate. In addition, the autonomy of adult life allows individuals to express their genetic predispositions to a greater degree than when their parents, teachers, and other authority figures were creating their environments and constraining their choices. The bidirectional nature of development is increasingly obvious in adulthood as interests, beliefs, and goals guide the direction and focus of actions, and these actions and their consequences in turn create the contexts for the revision of interests, beliefs, and goals. In the following sections, we review the concepts of social roles, the life course, and personal fulfillment, ideas that help explain the psychosocial dynamics of adulthood.

Social Roles

Social role is one of the concepts most frequently used for understanding adulthood. The major concepts of social role theory, which were introduced in chapter 2, are summarized in Table 11.1. We relied on concepts from social role theory frequently in the analysis of childhood and adolescent life stages, including chapter 7 when we discussed gender-role identification and again in chapter 10 when we examined individual identity versus identity confusion. The concept of role experimentation is the central process of that period. Clearly, many roles are learned and enacted during childhood. In adulthood, however, people assume multiple roles that expand their opportunities for self-expression and bring them into contact with new social demands. Adulthood can be seen as a series of increasingly differentiated and complex roles that the individual plays for substantial lengths of time. The salient roles of adulthood, such as worker, spouse, friend, parent, teacher, mentor, volunteer, or community leader, give structure to adult identity and meaning to life.

Bret's wife, Maureen, is already off to an early morning meeting. His daughter, Cheryl, is eating the breakfast that her mother left out on the counter for her. But she can't quite reach her milk. Bret is checking his emails and materials online for his first meeting while he talks to Cheryl's preschool to let them know that she will be picked up at noon by Suzie, her babysitter. Bret is getting pretty good at balancing the roles of husband, father, worker, and household manager. It's lucky they don't have a dog!

Social roles link individuals to their social environments. The roles that an individual plays exist as socially shared patterns of expectations for behavior. All roles can be characterized by costs and benefits that accumulate over time. For example, by assuming the role of worker, one has access to the benefits associated with the role, which might include social status, social support, health benefits, or financial resources. One also becomes responsible for meeting the expectations of the role, such as working for a certain number of hours each week or completing one's work to a certain standard of quality. Over one's life, the costs and benefits of the roles accumulate, influencing the ease or difficulty with which new roles and role transitions can be managed (Jackson, 2004). For example, if a person's worker role involves many short-term jobs with no retirement benefits, the transition to retirement may be more difficult financially, but the person may have less identification with a specific worker role and find the transition into

Table 11.1 Major Concepts of Social Role Theory

Concept	Explanation
Social role	Parts or identities a person assumes that are also social positions: kinship roles, age roles, gender roles, occupational roles
Role enactment	Patterned characteristics of social behavior generated by a social role
Role expectations	Scripts or shared expectations for behavior that are linked to each role
Role gain	Addition of roles
Role strain	Stress caused by too many expectations within a role
Role conflict	Conflict caused by competing demands of different roles
Role loss	Ending of a role; may result in stress and disorientation
Dimensions of life roles that vary from person to person	Number of roles Intensity of involvement in roles Time demands of each role Structure or flexibility of the role

© Cengage

retirement psychologically easier. As illustrated in the opening case, young adults may conclude that the costs of the worker role outweigh the benefits, and new work roles have to be discovered.

Roles are *reciprocal*, requiring complementary role identities—such as teacher-student, parent-child—in order to be enacted and sustained. Thus, participation in multiple roles brings with it a form of **social integration** and social support (Thoits, 2012; Wethington, Moen, Glasgow, & Pillemer, 2000). Involvement in multiple roles allows adults to help socialize younger generations. Only in adulthood do individuals experience the behavioral requirements of many of their roles, which in turn provide a basis on which to socialize their children for the demands of adulthood (Kite, 1996).

The expectations associated with adult roles provide a frame of reference within which individuals make their own personal decisions. For example, a man may know what is expected of him in the worker role, but he may choose to ignore those expectations and strive for greater responsibilities, more power, or more autonomy. People can conform to role expectations, revise them, or reject them altogether. In addition to the tensions produced by role conflicts and role strain, some of the stresses of adulthood result from the need to redefine certain role expectations in order to preserve an authentic sense of self.

Role theory offers several ideas about factors that may impede optimal growth or increase the risks for disruptions in development (Newman & Newman, 2016). First, individuals may be unable to meet role expectations due to physical, cognitive, or emotional limitations. For example, chronic illness or injury may make it impossible for a person to continue in a particular job. Severe postpartum depression may impair a woman's ability to parent her infant. Being too short, too tall, or having poor eyesight may prevent someone from following a desired career path.

A second factor that may place individuals at risk is the possibility of role conflict, role overload, or role strain. Especially in adulthood, individuals experience many highly demanding roles. When these roles are particularly salient, as with parenting and work roles, a person may find that he or she simply cannot meet all the expectations of each role adequately. Role strain is a form of stress that can result in physical and mental health problems.

A third factor that may result in risk is uncontrolled or unwanted role loss, like unemployment, widowhood, or nonvoluntary retirement. To the extent that a social role provides a structure for personal identity and social integration, role loss can bring serious problems of alienation and social isolation.

Life Course

Life course refers to the integration and sequencing of phases of **work** and family life over time. Glen Elder (1985, 1996; Elder & Giele, 2009; Elder & Shanahan, 2006), a leader in the elaboration of the life course perspective, described the two central themes of **trajectories** and **transitions**. A trajectory is the path of one's life experiences in a specific domain, particularly work and family. The family trajectory might include marriage, parenthood, grandparenthood, and widowhood. A transition is the beginning or ending of an event or role relationship. In the work trajectory, for example, transitions might be getting one's first job, being fired, and going back to school for an advanced degree. Transitions are the events that make up a lifelong trajectory. A person's work and family trajectories are embedded in a sociohistorical context. For example, for people born in the early 1920s, the events of World War II, occurring during their 20s, influenced their work and family formation. For many young men, the planned work trajectory was interrupted by military service, and many young women entered the labor market unexpectedly. At the close of the war, in the late 1940s and early 1950s, many couples who had delayed parenting started their families, which gave rise to the baby boom generation.

The life course concept can be applied to the content of individual life histories as they are expressed in a social and historical time period. Each person's life course can be thought of as a pattern of the adaptations to the configuration of cultural expectations, resources, and barriers experienced during a particular time period. One form of cultural expectations is what Bernice Neugarten and her colleagues (Neugarten, Moore, & Lowe, 1965) termed the **social clock**. This term refers to "age norms and age expectations [that] operate as prods and brakes upon behavior, in some instances hastening behavior and in some instances delaying it" (p. 710). Neugarten and her associates suggested that social class groups tend to agree on the appropriate age for significant life events, such as marriage, childrearing, and retirement. This consensus exerts social pressure on individuals in the group, pushing them to assume a particular role at an expected age. Age norms may also suppress behaviors that are considered inappropriate for one's age. Adults are aware of existing norms regarding the timing of certain behaviors and evaluate their own behaviors as being on time, too soon, or too late.

Implied in the notion of the social clock are expectations about **role sequencing**, the pattern or order of entry or exit from new roles and age-related role transitions. For example, European American adults in the United States tend to view an ideal sequence as work, marriage, and parenting, in that order. Research indicates that for women, following this sequence is associated with better mental health, including less depression and greater happiness in adulthood. Among African Americans, however, the sequence of work, parenting, and then marriage is associated with less depression and greater happiness. This suggests that different social norms for role sequencing may be operating in the respective ethnic communities (Jackson, 2004). The social clock is constantly being reset as people confront the challenges, demands, and new structures of modern society. For example, the age of first marriage in the United States is moving closer to 30; while it was very typical for young people in the 1960s to marry at age 21 or 22, very few college students today expect to be married at that age. In contemporary society, with the lengthening of the life expectancy and the increasing vitality of older adults, there are fewer and fewer domains in which a person is considered too old to participate (Neugarten, 1990).

FIGURE 11.1 ▶ provides a hypothetical view of the age-linked changes in occupational and family careers. line shows transitions in a family career. The line above shows transitions in an occupational career. Sometimes these transitions occur around the same time in life. For example, in Figure 11.1, marriage occurs during a period of job experimentation when a person may be changing jobs. This could create tension in the marriage if it results in economic insecurity. Occupational experimentation might be cut short in order to establish financial stability for the marriage. The conflicts that arise in coordinating these family and occupational careers may contribute to the high divorce rate in the first years following marriage. Considering adult lives in contemporary society, one can appreciate that this is only one possible map of the interconnections between work and family in the course of a life. The timing and overlap of occupational and family careers look quite different for the following people: a woman who extends her educational preparation to include a professional degree, works before marriage, and delays childbearing into her middle to late 30s; a woman who remains single and voluntarily childless, and dedicates her energy to excellence in a career; and a woman who marries right after high school, begins having children at age 18, works during her childbearing years, and then retires at 55 to enjoy her grandchildren and her personal freedom.

The pattern of the life course is influenced by the *historical era* (Schaie & Elder, 2005). The life course of a person who was born in 1900 and died in 1975, including the ages of completion of educational attainment, entry into the labor market, marriage, and retirement, would look quite different from that of a person born in 1930 and reaching age 75 in 2005. The two people would have gone through the same chronological ages, but during different periods of history, with different opportunities, expectations, and challenges. The first person would have been 30 at the time of the Great Depression. Her family could have been seriously influenced by loss of employment, difficulty in finding work, and loss of savings for retirement. The second person would have been 30 in 1960. Having served in the military during the Korean War, he would have been eligible for the GI Bill benefits to go to college, resulting in new occupational opportunities that contribute to occupational advancement during a booming economy (MacLean & Elder, 2007). There are many other possibilities of historical impact; these examples illustrate how historical factors might affect the life course.

All the people who are roughly the same age during a particular historical period are referred to as a **cohort**. The following list reflects the names given to particular generations in the United States and their estimated birth years. The cohorts are characterized by their shared exposure to historical events, prevailing economic conditions, and cultural/technological conditions (Robinson, 2016).

The Greatest Generation	1910–1925
The Silent Generation	1923–1944
Baby Boomer Generation	1945–1964
Generation X	1961–1981
Generation Y The Millennials	1975–1995
Generation Z	1995–2015

Differences in medical advances, occupational opportunities, educational resources, and the number of people in the cohort are four factors that may affect the pattern of life events for cohort members. Moreover, major crises, such as war, famine, and political unrest, may alter a trajectory by introducing unanticipated transitions—for example, closing off certain activities, as when young men interrupt their education to go to war, or opening up new opportunities, as when women enter the labor market because many of the men are in the military (Elder, 1986; Elder, Caspi, & van Nguyen, 1986; Elder, Shanahan, & Clipp, 1997).

The study of the life course focuses on the sequencing of events and the psychological growth that occurs as adults strive to adjust to changing and sometimes conflicting role demands. At different ages, people bring a distinct perspective to these events. For example, a crisis such as widespread unemployment may have a direct impact on the work trajectory of an adult, and also on the family environment or educational opportunities of a child. The person's developmental level and the particular developmental tasks and psychosocial crises that are most salient at the time will determine how a specific event will influence the life course.

Fulfillment Theories

As the norms and cultural expectations of modern life become more flexible, there is renewed interest in personal fulfillment and self-actualization as concepts that guide individual choices and directions for growth. The *humanistic* or *fulfillment* theorists emphasize the purposive, goal-oriented strivings that characterize adult life. The **fulfillment theories** have become integrated into the field of *positive psychology*, the scientific study of the strengths and virtues that enable individuals and communities to thrive (Seligman, 2011; Seligman, Parks, & Steen, 2006).

Charlotte Buhler was one of the earliest and most continuously productive of the humanistic or fulfillment theorists. Her work emphasized the centrality of life goals and intentionality through the life course (Buhler & Massarik, 1968). In her view, each person experiences life within a complex orientation to past, present, and future time. It is the hope for meeting future goals and for achieving a sense of fulfillment that prompts psychological growth. Buhler saw the years of early and middle adulthood as a time of setting definite goals and striving to achieve them. Toward the end of middle adulthood, there is focused preoccupation with the assessment of goals and the analysis of successes and failures. This process ends with a sense of fulfillment, partial fulfillment, or despair.

The last phase of life is seen as a reaction to this assessment. People may resign themselves to their successes and failures (as Erikson suggests in the concept of integrity). However, some people may be motivated to return to an earlier phase of striving to achieve unfulfilled goals or to undo past failures. Some people end their lives in a despondent state of unfulfillment, concluding that their existence has not been meaningful. Three concepts from fulfillment theory are especially relevant for understanding the directions of growth in adulthood: competence, self-acceptance, and self-actualization.

Competence

Robert White (1959; 1960, 1966) introduced the term **competence motivation** to explain behaviors that are motivated by a desire for new levels of mastery and control. People strive to increase their competence through repetition and practice of skills, by gaining new information, through education and training, and through feedback from earlier efforts at mastery. Exploration is a basic human behavior that results in opportunities to expand and extend the range of control in the environment. When exploratory actions result in new mastery or competence, they are accompanied by positive emotions of pride, satisfaction, and confidence (Heckhausen, 2011).

The competence motive can be seen in an infant's efforts at self-feeding even when those efforts result in less food making its way from dish to mouth. The competence motive can be seen in the determination of an adult to learn to ski despite the cold, the expense, and the sore muscles. It can be seen when retired persons enroll in adult education courses to expand their knowledge. Over the course of adulthood, competence is expanded through a deepening of interests, by pursuing information and experiences that contribute to what we often term expert knowledge. When goals are reached or deemed unattainable, the adaptive response is to disengage from the goal and set one's sights on new areas of mastery.

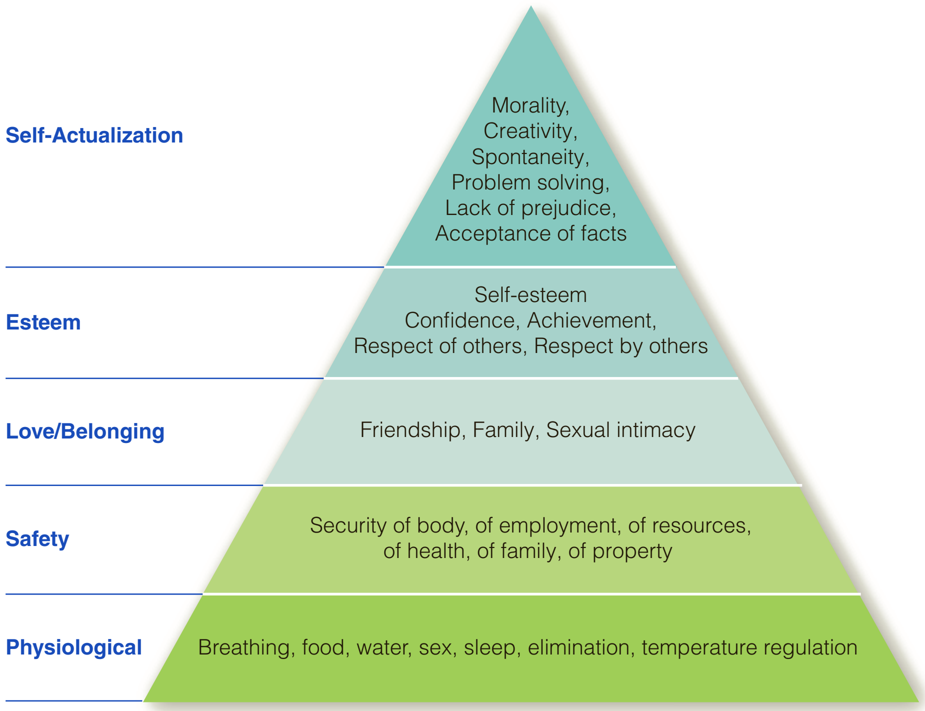
Self-Acceptance

According to Carl Rogers' theory of personality development, an essential component of continued growth is to experience and accept the authentic self (Rogers, 1959, 1961). This means achieving a sense of trust in one's ideas and impulses rather than denying or constantly disapproving of them. It means fostering acceptance and trust in relationships with others so that people bring their most authentic selves into interactions. **Self-acceptance** is a product of the positive feelings that come from being direct and from the acceptance one receives from others.

In Rogers' view, barriers to self-acceptance come largely from conditions that others place on their **love** or approval. If significant others give approval based only on meeting certain conditions, then the person learns to modify his behavior so that it conforms to those conditions. However, these modifications are made at the price of self-acceptance. They lead a person into a pattern of inhibiting or rejecting new thoughts and relying more and more on the opinions of others. The greater the discrepancy between the authentic self as one perceives it and daily experience, the more one is likely to experience life as threatening and stressful. The greater the harmony between the authentic self and experience, the more likely one is to experience a sense of trust, freedom, and creativity in daily functioning. An implication of this theory is that well-being is a product of person–environment coadaptation. In the search for self-acceptance, the person seeks social settings where his or her thoughts, beliefs, and actions are highly valued and where the social setting can be modified to value and endorse the talents of those who participate in it.

Self-Actualization

According to Abraham Maslow's theory, human beings are always in a state of striving (Maslow, 1968). **Self-actualization** is a powerful, growth-oriented motive that sits atop a pyramid of needs (see FIGURE 11.2 ▶). In Maslow's view, the primary human motives concern physiological needs, such as hunger, thirst, and



Self-Actualization
Morality,

FIGURE 11.2 ▶ MASLOW'S HIERARCHY OF NEEDS

a need for sleep. The second level focuses on safety and security—the need to find protection from dangers and threats. At this level, one might include security of employment, safety for oneself and one's family, and concerns about one's health and the health of one's family. As those needs are satisfied and maintained at a relatively stable level, people direct their energy to satisfying needs for belongingness and love, including friendship, intimate relationships, family and kinship ties, and desired group belonging. At the next level, one is motivated to enhance and protect self-esteem by building confidence in oneself, achieving valued goals, and gaining the respect and admiration of others. Finally, if those needs can be met and sustained, the person directs energy to self-actualization, a motive to make optimal use of one's full potential, to become a fully effective, creative participant in daily life. The need for self-actualization, like White's idea of competence, becomes a driving force, urging the person to seek new levels of insight and fulfillment. People who are characterized as self-actualized are described as authentic, having a reality-based orientation about themselves and others. They are spontaneous, interested in solving problems, and accepting of others. They lack prejudice. These qualities result from a continuous force toward growth as the richness of a person's human capacities are allowed to flourish (Maslow, 1943).

The fulfillment theories suggest that growth and maturation in adulthood are characterized by successful encounters with life challenges that result in a sense of purpose, meaning, and mastery. Building on the concepts of fulfillment theories, Carol Ryff developed a measure of psychological well-being, a multidimensional construct based on six dimensions: self-acceptance, quality ties to others, a sense of autonomy in thought and action, environmental mastery, purpose in life, and continued growth (Ryff, 1989; Ryff & Keyes, 1995; Seifert, 2016). Well-being, measured according to these dimensions, is associated with the capacity to sustain a positive outlook in the face of discrimination and adversity. A sense of meaning and purpose can support resilience in the face of illness and serve as a protective factor to reduce the risks of disease (Ruini & Ryff, 2016; Ryff, 2014).

In summary, the concepts of life roles, the life course, and fulfillment theories extend our understanding of psychosocial development in adulthood. Childhood is over. One addresses life with great expectations and exhilaration as well as the realization that there is serious work to be done. Young adults engage in intense and meaningful relationships in marriage or with intimate partners, friends, and coworkers. They attempt to cope with the complex challenges of daily life by balancing multiple roles. At the same time, they put into action the practices that express the values and beliefs to which they became committed at the close of later adolescence. They establish and revise goals, setting new standards for competence and self-acceptance. Over the course of adulthood, people return periodically to reflect on the meaning of their life and the value of their accomplishments. The expanding periods of later adulthood and elderhood provide new opportunities to seek self-actualization and moments of joy through intense dedication to personal and interpersonal achievements.

FURTHER REFLECTION: *Explain how the three theories—social role theory, life course theory, and fulfillment theory—extend psychosocial theory as a framework for understanding development in adulthood.*

Redcarpetpress/Alamy Stock Photo

Oprah Winfrey personifies Maslow's theory of self-actualization. She has overcome the challenges of her early childhood to found a business empire that has made her one of the wealthiest women in the world. Along the way she won an Oscar for her performance in the movie *The Color Purple,* became a model of integrity, dignity, generosity, and compassion through her philanthropic initiatives, and inspired American television audiences with the highest rated television talk show for 25 years. In 2013 she received the Presidential Medal of Freedom. In making this award to Oprah and others, President Obama reflected the essence of fulfillment theory in these words: "These are the men and women who in their extraordinary lives remind us all of the beauty of the human spirit, the values that define us as Americans, the potential that lives inside of all of us."

How does culture shape the way adulthood is defined? Based on your experience and knowledge, how do cultures differ in the milestones that mark adult status or maturity?

Developmental Tasks

We have identified the period from ages 24 to 34 as early adulthood. For many, this is a time of continued uncertainty as people begin to make essential commitments to work, relationships, lifestyles, and ideologies that express the content of their personal identities. The nature of early adulthood has changed dramatically over the past 60 years, from a time when young people moved with some deliberate focus into roles that they expected would be stable and long-lasting to a time of many more transitions and temporary commitments.

The current cohort of people in early adulthood have been given the label of Generation Y, or millennials. These young adults, born between 1975 and 1995, are children of the baby boom generation and have shared some of the following life experiences (Robinson, 2016):

- Grew up in a time when the majority of homes had a computer.
- Explosive growth in online companies such as Google, Facebook, Amazon, LinkedIn, and Paypal. Widespread use of cell phones and Internet services.
- The 9/11 terrorist attacks on the World Trade Center and the Pentagon, resulting in the Patriot Act, which permitted new, pervasive changes in security practices, surveillance, and monitoring of individuals. The attack also resulted in the invasion of Afghanistan, the search for Osama Bin Laden and other leaders of Al-Qaeda, and the removal of the Taliban.
- President G. W. Bush, Vice President Cheney, and Secretary of Defense Rumsfeld deceived the nation about Iraq having weapons of mass destruction, resulting in the invasion of Iraq.
- In 2008, the largest economic decline since the Great Depression, with many families losing their homes to foreclosures, and widespread unemployment.
- Growing consensus about global warming, an accompanying emphasis on energy conservation and eco-friendly products and consumer practices.
- Widespread changes in the workplace including increases in part-time, flex-time, and work from home with accompanying decreases in health care benefits and retirement benefits.
- An increasing divide in fundamental beliefs and values between the Republican and Democratic parties, resulting in a growing public frustration with government's inability to address important domestic issues.

Recall Figure 10.1 from chapter 10 that compared the percentage of young people who completed the transition to adulthood in 1960 to those who completed this transition in 2000. The five criteria for the transition to adulthood as defined in that figure are leaving home, finishing school, becoming financially independent, getting married, and having a child. By 2000, only 31 percent of men and 46 percent of women had made this complete transition by the age of 30. It is certainly possible to feel like an adult even if one has not completed all of these behaviors. Yet, for most young people, the list captures the essence of a cultural definition of adult status, and, as such, provides a framework for the psychological sense of maturity. In the 10 years from age 24 to 34, most young adults are striving to enact the key life roles of worker, intimate partner, community member, and parent that will reflect their ability to take responsibility for themselves, make important decisions about their lives, and begin to care for others.

The developmental tasks of this period have a lot to do with the person's ability to form effective relationships. The establishment of a sense of intimacy with a marital or cohabiting partner requires movement toward a greater sharing of personal feelings, secrets, and ways of looking at the world. Sometimes the demand is to listen; sometimes to listen and offer advice; sometimes to be understanding and helpful. Another set of behaviors that develops during this period involves establishing effective relationships at work. Getting along with associates, responding to authority figures, and having respectful relationships with clients or customers are keys to success. Parenting is another type of relationship of considerable responsibility. Becoming a parent is a role that most people are not terribly well prepared for, and as a result, there is a great deal of learning by doing. Becoming a parent means creating a new relationship that is distinct from any role in one's past—blending the caregiver, planner, and disciplinarian in a balance that changes frequently as the child matures. These three key relationships—intimate partner, worker, and parent—form the basic structure of the lifestyle that is enacted in early adulthood.

The pathway into adulthood is taking longer and is more diverse today than it was in the 1960s. Some young adults who do not go to college directly after high school may later enroll in college. Some later adolescents enter the military and return to civilian life to begin their early adulthood as veterans. The period of job experimentation is lasting longer, with many young adults making multiple job and career changes before settling into a career. The nature of the labor market is changing, with new occupations emerging and others falling away. The average age of entry into marriage is now the late 20s for women and the early 30s for men. Many marriages end in divorce. For many, early adulthood is a time of multiple intimate relationships. A significant percentage of early adults are in cohabiting relationships that do not end in marriage. Later age at marriage is associated with an older age for first childbearing. All these factors reflect a lifestyle in early adulthood that is more fluid and transitional than it has been in the past. At the same time, one must keep in mind the diversity of life stories. Some young adults assume significant role responsibilities, autonomy from their family, and self-sufficiency at relatively young ages. Others delay the typical commitments of adulthood well into their 30s and beyond.

Exploring Intimate Relationships

OBJECTIVE 2 Analyze the process of forming intimate relationships, including initial attractions, mate selection, and commitment to a long-term relationship. Contrast the ways that different patterns of cohabitation contribute to the formation of close relationships. Summarize the challenges one faces in adjusting to the early years of marriage.

The period of early adulthood is a time when men and women explore the possibility of forming relationships that combine emotional closeness, shared interests, a shared vision of the future, and sexual intimacy. Most young people become involved in romantic relationships that involve both sexual and emotional intimacy. Many forms of intimate relationships in addition to marriage are established including serious dating and **cohabitation** with or without the intention of marriage.

Marriage is one context in which work on intimate social relationships takes place. In 2015, 85 percent of the U.S. population had been married at least once by ages 40 to 49, and 96 percent had been married at least once by ages 75 to 84. The main change in the marriage pattern in the United States over the past 50 years is that more young adults postpone marriage until the end of their 20s. In 2015, 54 percent of women and 67 percent of men ages 25 to 29 had never been married. It is now normative for men and women to be single throughout their 20s (U.S. Census Bureau, 2015d, Table A1).

Delaying the age at marriage is related to other social trends, including having children at a later age, smaller projected family size, and, therefore, fewer years devoted to childrearing. Delaying age at marriage is also related to increased sexual exploration for single people. The 1980s brought the uncoupling of sexual activity, marriage, and childbearing. Younger age at entry into sexual activity and increases in rates of affairs and cohabitation suggest that even though many young adults do not marry, they become involved in intimate relationships during their twenties.

Readiness to Form Intimate Relationships

What factors are important in determining a person's readiness for a long-term commitment? From a psychosocial perspective, one can hypothesize that work on personal identity must be far enough along so that the possibility of a deep, emotional involvement with another person will be regarded as exciting rather than frightening. In studies of college students, a relationship has been found between identity status and the quality of intimacy. Students who had an achieved identity also reported the most genuine intimate relationships. In contrast, those who were characterized as identity confused were the least intimate and the most isolated (Montgomery, 2005; Seiffge-Krenke & Beyers, 2016). An overview of studies focusing on the relationship of identity and intimacy supports this relationship, although the link seems to be somewhat stronger for men than for women (Arseth, Kroger, Martinussen, & Marcia, 2009).

Early and later adolescents are likely to be thinking about intimacy issues long before their work on identity is completed. Thus, it makes sense to think that the capacity for intimacy emerges alongside identity work (Adams & Archer, 1994). However, when faced with dilemmas in which needs for identity and intimacy conflict, later adolescents tend to give identity issues higher priority. The following example and others like it were presented to adolescents to determine whether identity or intimacy would be the primary developmental issue guiding an important decision.

> Allison has been accepted to a very prestigious college with a reputation for a high-quality English department. She knows she wants to major in English. The main drawback to this college is that it is a 6-hour driving distance from her boyfriend. She also has been accepted to a college located within an hour away from her boyfriend, which has an average English department. She is unsure of which one to choose. How much

consideration should be given to each of the following issues in resolving this dilemma?

a. The quality of the program
b. The distance from her boyfriend

Why? (Lacombe & Gay, 1998, p. 801)

In this study, young people placed greater emphasis on the identity-oriented solutions, those that relate to the quality of the program and the importance of a high-quality education, rather than on the intimacy-oriented solutions. However, women were more likely than men to try to balance the two, seeking ways to meet identity and intimacy needs in the same solution (Lacombe & Gay, 1998).

In addition to identity achievement, school enrollment as well as educational and occupational aspirations are linked to relationship commitment. Young adults who are still in school are less likely to make a serious long-term commitment to an intimate partner, either through marriage or through cohabitation, than those who have completed school (Thornton, Axinn, & Teachman, 1995). Educational and occupational goals, and cultural views about the value of marriage create community expectations about the ideal age at marriage. The ideal age for marriage tends to be younger in a working-class community than in a middle-class community because expectations for continued education are not as great (Teachman, Tedrow, & Kim, 2012). In contrast, young people who attend college have a later timetable for marriage. Advanced education delays marriage more frequently for women than for men, perhaps because young women who have had more years of education have alternative means to secure economic resources. Nonetheless, college graduates are more likely to marry and less likely to intend to remain single than those who have never graduated from high school (Mahay & Lewin, 2007).

Readiness for a long-term intimate relationship may also be determined by other aspects of one's personal agenda, such as reaching a certain level of achievement in one's career, completing military service, or earning a certain income. Individuals with these ambitions are less likely to seek a long-term partner or to be receptive to expressions of love from someone than they may be once the goal is achieved.

Readiness to Marry

What determines whether an intimate relationship will end in matrimony? A basic factor is the person's underlying desire to marry. In the United States, most people hope to marry. In a national sample of individuals ages 18 to 89 in U.S. households, people who were single, heterosexual, and not in a steady romantic relationship were asked the following question: "If the right person came along, would you like to be married?" Over 3,000 respondents were categorized into five age groups: 18–24, 25–34, 35–44, 45–54, and 55–69. Answers were coded as yes or no. Overall, only 5 percent of respondents were single and had no desire to marry. This percentage was higher in the youngest age group (about 7 percent) and the oldest age group (about 10 percent), and lower in the three middle age groups (about 3 percent to 4 percent). In addition to age, having been divorced, having children, and not being employed were all associated with a lack of intention to marry (Mahay & Lewin, 2007).

In the United States, although expectations that one will marry are strong, young adults have the freedom to follow their own timetables for marriage and choice of a partner. Cultural values of individualism and autonomy provide support and justification for addressing personal goals prior to making a commitment to an intimate relationship. With greater geographic mobility, young adults are more likely to make nontraditional partner choices, including interracial and same-sex unions (Rosenfeld & Kim, 2005). However, in some ethnic groups, such as Asian Indians and Arab Americans, there is still a strong expectation that parents will guide the selection of a marriage partner. In other groups, such as the Mormons, the high value placed on sexual abstinence prior to marriage results in an earlier age at marriage than for other groups (DeGenova, 1997).

Phases in the Selection of a Partner

In the United States and other individualist cultures, most people believe that **romantic love**, usually defined as a combination of physical attraction, exhilaration in the presence of the loved one, and a strong desire to care for, protect, and be physically close to the loved one, is the central reason for choosing a marriage partner. In societies with a more collectivist orientation, romantic love is not necessarily relevant to the selection of a partner. In these cultures, the choice may be made by family members, based on religious, financial, or family background factors believed to contribute to a good match, not only for the person, but also for the extended family system. In these cultural groups, the principle of **endogamy**, or marriage within one's well-defined group, is encouraged. An Asian Indian college student of Muslim faith describes her orientation toward marriage:

> A few years ago I fell in love with a Hindu guy, but after a while I realized I had to end the relationship. My mom, it would have broken her heart. I care too much about my family. People would look down on my parents if I married outside of our religion. . . . Muslims are good people. We are very focused. We have morals. I want to give my children that sense of identity. So I'm comfortable waiting until I meet an acceptable Muslim man. (Belsky, 1997, p. 279)

FIGURE 11.3 ▶ provides a theoretical model including four phases of increasing involvement in the mate selection process (Adams, 1986). The model suggests a dynamic process where movement toward new levels of intimacy and commitment can be advanced or deterred depending on how the partners interact, the nature of alternative attractions, and the social contexts that support or undermine the relationship. At each phase, the relationship may be terminated if the key issues produce undesirable information or negative assessment of the partner. Also, the relationship may end if an alternative attraction becomes so strong that it reduces investment in the first relationship. The alternative attraction may be another person, a job, school, or the desire to achieve a personal goal. In contrast, investment in the relationship may increase if no attractive or acceptable alternatives are available (Stanley, Rhoades, & Whitton, 2010).

FIGURE 11.3 ▶ THE MATE SELECTION PROCESS IN THE UNITED STATES

Source: Based on Adams, 1986.

Phase I: Original Attraction. Phase I, original attraction, captures the early process of partner identification. *Initial impressions* are formed in the first few seconds of an interaction. Many of these cues are captured through eye contact and a scan of a person's face (Jones et al., 2010; Perrett, 2012). Several brain circuits are involved in this rapid evaluation. One system is activated more when the face is a person of the desired sex; one system is activated when the face is attractive as compared to unattractive; and one system is activated when the person is judged as a "good match for me" (Cooper, Dunne, Furey, & O'Doherty, 2012; Hahn & Perrett, 2014). The positive "reward value" of these faces at the neural level has motivational implications. The observer is willing to expend more effort to see the face again, suggesting a path toward repeated contact.

In an experimental study, women were shown pictures of men's faces. These same men had been assessed as to whether they preferred pictures of adults or pictures of infants. Their testosterone levels were assessed using a saliva sample. Women were shown the photographs of these men and asked to rate them on four dimensions: likes children, masculine, physically attractive, and kind. They were also asked to rate each man's attractiveness as a short-term romantic partner and as a long-term partner in a committed relationship. Based on facial cues alone, women were able to differentiate the men who preferred the pictures of infants from those who preferred pictures of adults. From these photographs women also rated the men who had higher testosterone levels as more masculine. In their assessment of short- and long-term relationships, the photos that women rated as more masculine and physically attractive were the ones they rated most highly for a short-term relationship. The photos women rated as kind, likes children, and physically attractive were most highly rated for a long-term relationship; masculinity was no longer a salient feature for these ratings. Research supports the view that for women, initial attraction can be based on facial cues and that the importance of various cues depends on the kind of relationship the woman is seeking (Roney, Hanson, Durante, & Maestripieri, 2006).

The principle of **homogamy** means that people are attracted to others who share important areas of similarity. Three salient aspects of similarity are race, religion, and educational level. In a study of three levels of relationship commitment—sexually intimate partners, cohabiting couples, and married couples—the couples showed high levels of similarity (Blackwell & Lichter, 2000, 2004). However, similarity extends beyond these basic demographic characteristics. For example, in a study of dating and mating preferences among college students, women preferred to date men who were similar to them in education and occupational level and preferred to marry someone who was also similar in religious values and desire for children (Knox, Zusman, & Nieves, 1997). Other studies show that couples are similar in their preferences for leisure, their political orientation, and whether their parents had been divorced or not (Wolfinger, 2003).

In a study of 12,000 Dutch couples, partners were found to be significantly similar with regard to health indicators. Individuals whose partners were in poor health were significantly more likely to report being in poor health themselves than individuals whose partners were in good health. Although there were patterns of accumulated health problems within households, the young couples who had been together only a short time were just as similar in their health as older couples who had been together for years. The researcher concluded that the similarity in health status was more a result of initial similarities than a product of the impact of shared circumstances over years of marriage (Monden, 2007).

Partners are selected from among those who are available for interaction. In the most general sense, the choice of a partner depends on the network of interactions in which one is involved. Many of the choices one makes during adolescence and young adulthood—such as where to go to college, where to work, which activities and social functions to attend, and where to take a vacation—determine who one meets. People who occupy similar settings such as neighborhoods, college environments, work settings, or religious institutions are likely to be similar in certain characteristics that contribute to the observed homogamy in couples (Kalmijn & Flap, 2001). People who do not perceive themselves as having desirable qualities or who view the pool of potential partners as undesirable are more pessimistic about finding a partner and may not be very active in seeking out romantic encounters (Bredow, Huston, & Glenn, 2011).

Some early adults are in situations in which it is difficult to find suitable mates. They might move to a new town for a job, return home after serving in the military, or be employed in a career that leaves little time for social life. The problem they face is how they are going to meet people and begin the dating process. Online dating is one strategy to expand access to potential partners. From 2013 to 2015, the use of online dating and mobile apps to find romantic partners has nearly tripled. A recent survey found that 22 percent of those in the age range 25 to 34 have used these services to identify potential partners, and about one third of respondents in this age range knew of someone who formed a long-term relationship through an online dating service (Pew Research Center, 2016).

Demographic realities influence the possibility of meeting suitable partners. In each community, for each age group of heterosexual women, the number of suitable, available male partners may differ, depending on such characteristics as the educational level, employment opportunities, and racial composition of the men in that community. For example, declines in the marriage rates for African Americans is linked to the decline in the availability of appropriate African American male partners. Single, never-married African American women increased from 17 percent of the total female African American population 18 years old and older in 1970 to 46 percent in 2014 (U.S. Census Bureau, 2015d, Table A1). This pattern is related in part to the high rates of mortality and imprisonment of African American men and in part to their economic marginality (Kaiser Family Foundation, 2006).

Once two people meet, what factors support their continued involvement? One's style of interaction—for example, whether one is shy and withdrawn or expressive and outgoing—influences the number and kinds of interactions one has with others. In contrast to the principle of homogamy, which emphasizes the role of similarity in the attraction process, **social evolutionary theory** suggests that men and women differ in the features they emphasize in evaluating someone as a desirable partner. The evolutionary perspective highlights the reproductive potential and the reproductive investment of one's partner. *Reproductive potential* refers to the physical, material, and social resources that a partner may be able to contribute to one's fertility and childrearing. *Reproductive investment* refers to the willingness of a potential partner to commit these resources to one's children. Men tend to emphasize the biological or physical resources of a potential partner, valuing youth and physical appearance in a partner more than do women. Women tend to emphasize the social status and economic resources of a potential partner, valuing earning potential and job stability in a partner more than do men (Geary, Vigil, & Byrd-Craven, 2004).

In a cross-national study of heterosexual mate preferences in samples collected in Africa, Asia, Australia, Europe, New Zealand, and North and South America, David Buss (2003) found that men placed more emphasis on a partner's youth and physical appearance, whereas women placed more emphasis on a partner's financial prospects, dependability, and industriousness. In addition to physical appearance and social status, people who behave in an admirable, effective manner may be viewed as attractive or desirable. People seek others who will support their goals, who can be encouraging and positive, and who appear to be able to collaborate effectively in shared experiences (Sanders, 1997).

Phase II: Deeper Attraction. Phase I, *original attraction*, moves on to Phase II, *deeper attraction*, as the partners begin to disclose information about themselves, interact in ways that deepen the relationship, and discover areas of important similarity. In Phase II, the discovery of basic similarities and a feeling of rapport are central to continuing the relationship (Bredow, Kate, & Huston, 2008).

— CASE STUDY Hannah and Matt: An Online Dating Couple's Story —

This case illustrates the process from first attraction to deepening commitment in the context of a relationship that started through an online dating service.

The way we met was actually a happy accident. I had not changed my location settings or my age settings from the default, so Matt kind of snuck in there, because there's a 13-year age difference and we lived 50 miles apart. So we got a match, but neither of us was really taking it seriously. Matt messaged me, and we talked a little bit, and just kind of got everything big, all of our baggage, out right away so we could see if it was even worth continuing to talk. I gave him my phone number and he texted me, "Hi, Hannah, it's Matt." And I said: "Which Matt?" as a joke. And that was it. We just talked nonstop from that point, and we went on our first date a week later. We went on a hike, and we put wine in water bottles and had a little picnic at the end of the hike.

Neither of us was looking for anything super-serious, but we kept hanging out regularly and it just kind of happened without either of us noticing. I have a son from a previous relationship—Jackson, he was 2 at the time—and they met and just really hit it off. I knew from the first date that I really, really liked Matt. It was great, because I couldn't get out a lot at the time—I could get out maybe once a week, if I had a babysitter. And you're not going to meet somebody at a bar if you're a single mom. So it saved me from meeting a lot of duds.

Five months into dating, he proposed, but we had already been talking about it for a few months. He had met my son, so we had to ask: Do we have a future? Is it worth dating and building a relationship with Jackson? We decided it was worth it, obviously. I'm grateful. I don't know what I did to deserve this, but I'm just going with it.

CASE ANALYSIS Using What You Know

1. Based on what you have read, what factors might have moved this relationship from initial interest to deeper attraction?
2. How does this case illustrate the idea of readiness to marry?
3. Have you ever tried online dating? What were your hopes or goals for this experience? How well were they met?
4. Hannah says that being a single mother made online dating a very valuable tool for meeting potential partners. What might be some other life conditions that could contribute to the appeal of using an online dating site?

Each person has key values and background characteristics that serve as a filter for assessing whether the other person is an eligible partner. Of course, eligibility is defined differently by different people. For some, any person who is conscious is eligible. Others have criteria that limit the choice of a marriage partner to someone of a certain age range, religion, race, educational background, and family history. Some adults would not consider marriage to someone who does not share their religious faith. Only members of their own religious group are perceived as eligible partners. Research conducted on religious homogamy finds a consistent relationship between the extent to which partners have similar religious beliefs and participate together in religious practices and their marital quality. However, over the past 20 years, this relationship has been weakening. Agreement about gender ideology, partner participation in the labor market, and agreement about the balance of work and family roles have emerged as salient values that rival religious values.

There are many dimensions along which two people may recognize similarities or differences. They may seem quite different on some dimensions, such as religion and social class, yet discover that they are quite similar on others, such as life goals and political ideology. For example, partners who have similar ideas about gender roles and how men and women ought to function in a marriage are likely to be drawn to one another. The more aware individuals are of the themes that are central to their own sense of personal identity, the better they can recognize the dimensions of similarity and difference in other people that will contribute to intimate relationships.

The process of finding partners who are similar in important values, goals, and lifestyle is incorporated into most online dating services. Rather than going through a gradual process of learning about someone through conversations, frequent or periodic interactions, and the gossip or wisdom of other people who know the person, the user can learn a lot of information about someone all at once and decide if that other person is worth pursuing in a face-to-face meeting. Through the use of a mathematical algorithm, online dating services identify potential partners who appear to be a good match for one's salient preferences (Finkel et al., 2012).

Many people may not even be aware of their own criteria for the eligibility of potential partners. For example, most heterosexual men expect to marry women who are a few years younger than they are. Although they do not deliberately state this as a criterion for marriage, they simply do not interact with or feel drawn to a partner who is perceived as too old. Similarly, if heterosexual women are looking for a long-term commitment, they tend to seek partners who are a few years older (Buunk et al., 2001).

Most people seek intimate partners who will understand them and provide a sense of security and emotional support. The attachment theory of romantic relationships expands on infant-caregiver attachment research. The seeds of one's expectations and mental representations about close relationships are formed in infancy through the quality of early care one received. Building on this early experience, the three features of attachment—secure, anxious, and avoidant—can be seen in the ways that adults approach romantic relationships. If you think back to the attachment system, its primary function is to provide reassurance about safety and security, especially under conditions of threat or stress. In a secure attachment, the mere physical presence of a loved one, as well as comforting words and touch, can reduce feelings of pain and distress. However, the anxiously attached person is constantly vigilant to potential loss, fearing rejection or abandonment. The avoidantly attached person downplays the importance of close relationships and tends to suppress emotional reactions in order to prevent being harmed by messages of rejection (Feeney, 2016; Zayas & Sellcuk, 2013; Zayas, Mischel, Shoda, & Aber, 2011). The **Applying Theory and Research to Life** box on attachment styles provides a way of understanding how implicit attachment representations influence the way people move toward or away from potential partners.

In addition to the preferences that individuals express about potential partners and the availability of those partners in a particular community, third parties can play a role in the progression or termination of a relationship during Phase II (Kalmijn, 1998). Family members can help enhance a partner's attractiveness if they are enthusiastic about the partner and encourage the relationship. As the earlier example of the Muslim college student illustrated, parent and family reactions can also interfere with a deepening attraction if the potential partner meets with family disapproval.

Research on interethnic dating has shown how social network diversity contributes to the likelihood of college students

APPLYING THEORY AND RESEARCH TO LIFE

Attachment Styles and Relationship Formation

Attachment theory is an influential framework for understanding the process of relationship formation in adulthood. One's attachment style, established in infancy, provides a template for orienting toward intimate relationships in adulthood. Anxiety over abandonment, comfort or discomfort with closeness and emotional disclosure, and the level of self-esteem associated with a secure or insecure attachment contribute to the type of partner one seeks and one's ability to sustain an intimate relationship. The threat of loss of access (both physical and emotional access) to an intimate partner is likely to produce anxiety, protest, and steps to regain proximity (Feeney, 2016; Shaver & Mikulincer, 2011).

Bartholomew (1990) developed an attachment typology based on one's attachment experiences in infancy and toddlerhood. One can have a positive or negative assessment of the self, and a positive or negative assessment of others (see Table 11.2).

Secure individuals have a positive model of themselves and of others: "It is easy for me to become emotionally close to others. I am comfortable depending on them and having them depend on me."

Preoccupied individuals have a positive model of others, but a negative model of the self: "I want to be completely emotionally intimate with others, but I often find that others are reluctant to get as close as I would like. I am uncomfortable being without close relationships, but I sometimes worry that others don't value me as much as I value them." Preoccupied individuals are both anxious about rejection and dependent on others for reassurance. When one or both partners are characterized by a preoccupied attachment, the likelihood of abuse in the relationship increases (Henderson, Bartholomew, Trinke, & Kwong, 2005).

Dismissing avoidant individuals have a positive model of self, but a negative model of others: "I am comfortable without close emotional relationships. It is very important to me to feel independent and self-sufficient, and I prefer not to depend on others or have others depend on me." Dismissing avoidant individuals are low in anxiety, and also reluctant to get too close to others.

Fearful avoidant individuals have a negative model of both self and others: "I am uncomfortable getting close to others. I want emotionally close relationships, but I find it difficult to trust others completely, or to depend on them" (Crowell, Fraley, & Shaver, 1999, p. 451). These individuals are both socially avoidant and anxious about loss and rejection.

The secure and the dismissing individuals have high self-esteem; however, they differ markedly in the value they place on intimacy and in their interpersonal style. Secure individuals value relationships and are viewed as warm and nurturing. In contrast, dismissing individuals minimize relationships in favor of self-reliance and are viewed as cold or competitive. The fearful avoidant and the preoccupied individuals lack the self-esteem of the secure or dismissing groups. However, the fearful individuals avoid social contact, whereas the preoccupied individuals try hard to engage in relationships.

Table 11.2 The Attachment Typology

		Working Model of Others	
		Positive	**Negative**
Working Model of the Self	**Positive**	Secure	Dismissing avoidant
	Negative	Preoccupied	Fearful avoidant

Source: Based on Bartholomew, 1990.

Although it may seem obvious that partners who both have secure attachment styles will enjoy a stable, trusting, and satisfying relationship, other combinations have been found to form stable relationships as well. Not everyone is looking for a partner with a secure attachment. The relationships of anxious women and avoidant men are quite stable. These relationships reflect gender-role stereotypes in which women work hard to be nurturing while men are more distant and pull away from conflict or intimate disclosure (Feeney, 2008).

The context of the relationship may also alter one's characteristic attachment responses. When a close romantic relationship is perceived to be deteriorating, insecure avoidant behaviors may increase, even among those who have a secure attachment style (Gillath & Shaver, 2007). In contrast, over time a person with an anxious attachment can be reassured when a partner is caring and trustworthy.

> I had a real problem trusting anyone at the start of any relationship. A couple of things happened to me when I was young, which I had some emotional difficulties getting over. At the start of our relationship, if P. had been separated from me I would have been constantly thinking: "what was he doing?"; "was he with another girl?"; "was he cheating on me?"; all that would have been running through my head. Over a 3-year period of going out, you look at it in a different light; you learn to trust him. (Feeney, 2008, p. 465)

Critical Thinking Questions

1. Summarize the similarities and differences between the attachment styles described in infancy and those described here regarding adult romantic relationships.
2. Imagine that people have been set up on a blind date. How might the following couples get along?
   - Secure and Dismissing
   - Secure and Preoccupied

- Preoccupied and Fearful Avoidant
- Dismissing Avoidant and Fearful Avoidant

3. Critically evaluate the model proposed in this analysis of adult attachment style. What are some strengths and weaknesses of this typology? What aspects of the attachment construct are omitted in this approach?
4. Invent your own model for characterizing adult orientations to romantic relationships. How much would you rely on the attachment paradigm for this model? What other conceptual themes might you draw on to classify how people approach intimate relationships?
5. Generate a model of intimate relationships that incorporates dimensions of culture. How might people with more independent or interdependent views differ in the type of partner they seek?

dating across ethnic boundaries (Clark-Ibanez & Felmlee, 2004). Students who had an ethnically diverse group of friends were significantly more likely to have had one or more experiences with interethnic dating relationships. Students of color and male students were more likely than White or female students to have had experiences of interethnic dating. Those students whose parents had a diverse group of friends were most likely to respond that they had experienced interethnic dating more than once or twice. In the open-ended responses, students were asked how easy or how difficult it might be to date someone of a different ethnic group. The majority mentioned social pressures and social networks in their responses. For most of the students, the social network exercised pressures against interethnic dating. As one Korean American student wrote, "My parents, just as most Korean parents that I have contact with, banish the idea of interracial dating." However, those who say it would be easy to date across ethnic lines often mention the role of friends and associates: "It is easy to date interethnically. I see people of different ethnicities every day. I'm used to them" (male Latino American).

Phase III: Role Compatibility and Barriers to Break Up. The relationship is likely to proceed from Phase II to Phase III if the partners extend the domains in which self-disclosure occurs, including sexual needs, personal fears, and fantasies. With each new risk taken, the discovery of a positive, supportive reaction in the partner deepens the level of trust in the relationship. The discovery of **role compatibility** and empathy gives the relationship a life of its own. Role compatibility is a sense that the two partners approach a situation in ways that work well together. Whether it is a visit to a relative's home, an office party, a casual evening with friends, or running out of gas on the highway, the two people discover that they like the way each behaves and that their combined behavior is effective. Empathy builds through these observations, enabling each partner to know how the other responds and how to anticipate the other's needs. Here we see one of the significant limitations of online dating algorithms. They can be useful in finding matches, but once two people begin to interact, the algorithms are not able to predict how well they will face real life, new situations together (Finkel et al., 2012).

One aspect of this new level of intimacy is the special way in which romantic partners interact with one another. In affectionate and playful exchanges, partners often use baby talk, a type of gentle, high-pitched register, in which features of words are altered and new vocabulary may be created. Partners may give one another affectionate nicknames and create unique signals for communication. The establishment of this intimate communication system acts as another bond between the couple, creating a personal environment that is not shared with and often not even known to others (Bombar & Littig, 1996). At some point in Phase III, partners may begin to think that they are in love. They may even tell each other, "I love you."

In addition to the growing sense of compatibility, barriers to breaking up help consolidate the relationship. First, the partners have disclosed and taken risks with each other that they probably have not taken with others. Second, they have achieved

As role compatibility and empathy grow, the relationship takes on a new degree of intimacy and the couple begins to conceptualize a future together.

Andy and Jennifer take a moment to celebrate their decision to move in together. What factors will influence the future of this cohabiting relationship?

Ingram Publishing/Alamy Stock Photo

comfortable feelings of predictability and empathy that make them more certain about each other than about possible alternative attractions. Third, once a person has become an object of romantic attachment, closeness to that person is accompanied with feelings of safety and trust. The attachment system operates to motivate the partners to maintain physical and emotional closeness. Strong feelings of loss and anxiety are likely to be associated with the possibility of disruption to this relationship. Fourth, the partners have been identified by others in their social network, including family and friends, as a couple. Support from one's social network provides a stabilizing force that may be especially important for couples in nontraditional relationships. Other barriers include procedures needed to end the relationship, such as moving to a new apartment or dividing up or selling off shared purchases, and the feelings of obligation that may have accompanied earlier expressions of love and sexual intimacy (Kurdek, 2006a). At this point, the costs of breaking up begin to be quite high, including loss of a confidant, a companion, and disruption or even disapproval in their social network.

Phase IV: The Right One Relationship. Once the partners enjoy role compatibility and empathy, they move on to Phase IV, *the right one relationship*. Two processes unfold that contribute to the intensification of this romantic attachment: the positivity bias and the similarity bias. The **positivity bias** refers to the tendency to view one's romantic partner in an overly positive light. This bias contributes to the perceiver's belief that he or she has indeed found the absolutely perfect partner. It also makes the partner feel valued and cherished (Rusbult, VanLange, Wildschut, Yovetich, & Verette, 2000). The **similarity bias** refers to the tendency to exaggerate perceptions of similarity between partners, thereby increasing feelings of closeness and being understood (Kenny & Acitelli, 2001). Both the positivity bias and the similarity bias are associated with the perceiver's satisfaction in the romantic relationship, thereby reducing the likelihood that an alternative attraction will deter the person from making a long-term commitment (Luo & Snider, 2009).

The right one relationship is characterized by both romantic love and friendship. The intensity of romantic love has been documented in studies that contrast romantic love and friendship. Lovers describe their relationships as characterized by *fascination*, *exclusiveness*, and *sexual desire:* "I would go to bed thinking about what we would do together, dream about it, and wake up ready to be with him again" (Davis, 1985, p. 24). They also express more intense caring for their loved ones than for friends. This caring includes giving their utmost, even to the point of self-sacrifice. The intensity of these characteristics accounts for some of the specialness and unsettling euphoria associated with being in love. It may also explain the relative instability of love relationships. Intense emotion is difficult to sustain. In contrast, friendship or companionate relationships reflect a high level of **disclosure** and a sense of having shared many life experiences. This leads to a sense of truly knowing the person, experiencing mutual understanding, and being concerned about each other's welfare (Driver, Tabares, Shapiro, & Gottman, 2012).

Even with the help of this model, the final step of commitment to marriage is not easy to understand. In today's society, many young couples agree to live together and make a commitment to their partnership without marriage.

Cohabitation

Cohabitation has become an increasingly common practice for people in early adulthood. In 2014 there were 6.7 million unmarried, opposite-sex couple households in the United States, and over 783,000 unmarried same-sex couple households (U.S. Census Bureau, 2014). What is the nature and meaning of cohabitation? Is it an informal alternative to marriage, or more like singlehood, except with ongoing bond of connection to a partner?

In a cross-national comparison of opposite-sex couples, six types of cohabiting relationships were described (Heuveline & Timberlake, 2004, pp. 1216–1218):

1. *Marginal*. Cohabiting is infrequent, its duration short, and few children are born within this relationship because the cultural norms strongly discourage this kind of union.
2. *Prelude to marriage*. In the face of high divorce rates, cohabiting may be viewed as a way for couples to test the relationship prior to marriage. The duration of cohabitation should be relatively brief, frequently transition into marriage, with few children born to cohabiting couples.
3. *Stage in the marriage process*. Couples in this type of relationship may see some disadvantages to marrying immediately, but they do intend to marry. Childbearing

in the context of this relationship is more common, because the partners expect to marry. The relationships are of longer duration than in type 2, more often involve childbearing, and end in transition to marriage.

4. *Alternative to being single*. Couples want to postpone marriage and family formation, perhaps because they think they are too young to marry. These couples are more like single, dating couples than like married couples. These relationships should be relatively short in duration, end in separation, and few children are born in these relationships.
5. *Alternative to marriage*. Couples view cohabiting as an alternative to marriage. These relationships are often established in the context of cultural support for children born outside the bonds of marriage. These relationships are of long duration, less likely to transition into marriage, and more likely to involve children.
6. *Indistinguishable from marriage*. Because of the cultural acceptability of unmarried couples and institutional support for all parents, couples consider cohabitation versus marriage on pragmatic grounds. These relationships are not a conscious alternative to marriage based on attitudes or values. The relationships are likely to involve children, but they may be of shorter duration than in the alternative to marriage, if only because many of them do transition into marriage.

The cross-national comparison was based on data from 14 European countries plus Canada, New Zealand, and the United States. Cohabitation among never-married women is comparatively rare in Spain, Italy, and Poland (less than 15 percent) and quite common in France, Finland, New Zealand, and Sweden (more than 60 percent). The median duration of cohabiting relationships is 3 years or longer in France, Sweden, and Canada, and comparatively short in the United States where the median duration is 1.2 years. Across 11 countries where there are substantial numbers of cohabiting relationships, 61 percent of these relationships end in marriage. In comparison, 64 percent of Canadian cohabitation relationships end in separation, as do 52 percent of cohabitation relationships in the United States.

Using the indicators of incidence of cohabitation, proportion ending in marriage, and incidence of children born to mothers in a cohabiting relationship, the researchers tried to match countries with the six types of cohabitation most characteristic of their population. In Italy, Poland, and Spain, cohabitation was considered marginal. In Belgium, the Czech Republic, Hungary, and Switzerland, cohabitation was most likely a prelude to marriage. In Austria, Finland, Germany, Latvia, and Slovenia, cohabitation was a stage in the marriage process. In New Zealand and the United States, cohabitation was an alternative to being single. In Canada and France, cohabitation was an alternative to being married. In Sweden, cohabitation was indistinguishable from being married. The authors warned, however, that these national patterns may not reflect all the differences that are present within a culturally diverse society such as the United States (Heuveline & Timberlake, 2004). As an example, among Latino couples in the United States, those who share the same religious faith and who frequently attend religious services together are likely to experience a stable, cohabiting relationship (Petts, 2016). These comparisons provide a frame of reference for interpreting the meaning of cohabitation in national contexts. They illustrate differences in cultural support for varying patterns of family formation by highlighting the frequency, duration, and path of cohabiting relationships.

Consensual union without a civil or religious marriage has been practiced in Latin America for centuries and is regarded as a form of marital union (Martin, 2002). For a variety of economic, political, and religious reasons, some couples were not able or willing to meet the formal or religious requirements of marriage. They entered into an informal but no less stable relationship. Women who had a child within such a relationship were more likely to describe it as informal marriage than as cohabitation. Women who had been married before were also more likely to describe their current relationship as informal marriage rather than cohabitation. It appears that consensual unions were perceived by women to be more like marriage than like singlehood. Long-term cohabiting couples are very similar to legally married couples with regard to the frequency of conflict, perceptions of equity, and relationship satisfaction (Willetts, 2006).

Even though cohabitation has become increasingly common in the United States, there is a consistent finding of a negative relationship between cohabitation and marital quality and stability. Individuals who have cohabited in the past have more conflict in their marriages, less marital happiness, and a greater probability of divorce. These findings have been repeated for cohorts of couples who married between 1964 and 1980 when cohabitation was less common, and those who married between 1981 and 1997 when cohabitation became more frequent (Dush, Cohan, & Amato, 2003). The relationship was observed in a meta-analysis involving numerous studies of premarital cohabitation and marital stability (Jose, O'Leary, & Moyer, 2010). However, the relationship of cohabitation and marital instability was not found for couples who married their cohabiting partner, suggesting that for these couples, the cohabiting experience was in fact a stage in the marriage process. More research is needed to understand why those who cohabit and then go on to marry someone else experience less marital satisfaction and greater marital instability.

Close Relationships Between Partners of the Same Sex

In many respects, the same dynamics that influence the formation of close relationships among opposite-sex couples apply to same-sex couples. Nonetheless, gay and lesbian couples face certain unique challenges that are not typically present for heterosexual couples: They often have to establish their relationship in a context of secrecy, they often experience disapproval from their family, and until very recently, many states refused access to legal recognition of their union should they desire it (Kurdek, 2005). Now, with the passage of the Supreme Court ruling of *Obergefell* v. *Hodges* in 2015, marriage between same-sex couples is viewed as a constitutional right that is to be respected across all states in the U.S. In the months following the Supreme Court ruling, the Gallup Poll reported increases in the percentage of same-sex couples who are married, both in states where it

Courtesy of Philip Newman

As two professional women creating a life together, Jenny and Rachel have to invent many aspects of their relationship, but they do not have to invent the wonderful feelings of being in love.

had previously been legal and in states where it had been illegal (Jones & Gates, 2015).

Lesbian and gay relationships are similar in many respects and distinct in others. Lesbian and gay couples who are in a committed relationship tend to give great priority to maintaining and enhancing their relationship for several reasons. First, they share the conflicts around coming out and the complications that this poses in family and work settings. This provides a common bond and a need to protect the relationship from detractors. Second, because of the nontraditional nature of same-sex relationships, the partners have to invent many of the details of their relationship, thus making it more salient and less scripted than heterosexual relationships. Finally, they face ongoing challenges, such as the complexities associated with the decision about whether and how to have children and how to ritualize their commitment to one another (Mohr & Jackson, 2016).

In a comparison of gay and lesbian couples, the two types of couples were similar in many respects (Kurdek, 2003). They had similar approaches to conflict resolution, similar experiences with support from their social networks, and similar rates of dissolution or instability in their relationships. The same variables predicted relationship dissolution for gay and lesbian couples. Lesbian couples were more alike than gay couples at the start of their relationship and scored higher on measures of liking their partners, trusting their partners, and perceiving equality in their relationship. Overall, lesbian couples had higher rates of relationship satisfaction. This finding is puzzling given that lesbian and gay couples had the same degree of stability. However, it may be explained by observations that lesbian couples have somewhat lower levels of attachment anxiety, which can produce relationship distress (Mohr, Selterman, & Fassinger, 2013).

Lesbian relationships often emerge out of close, same-sex friendships. Lesbians are somewhat more likely to be able to establish long-term relationships than gay men. Most lesbians describe their relationships as stable, sexually exclusive, and extremely close. They also describe their relationships as closer and more flexible than do gay men or heterosexual couples (Green, Bettinger, & Zacks, 1996). Greater levels of satisfaction in the relationship are associated with greater levels of equality and shared decision making. Equality in the relationship depends on equal resources and commitment to the relationship (Eldridge & Gilbert, 1990). In comparison with women in opposite-sex marriages, women in lesbian relationships are more likely to describe greater satisfaction in their sexual activity and greater dissatisfaction with inequalities in the relationship. These women place a strong value on companionship and on confiding in one another, but they also expect to experience high levels of autonomy within their relationships.

Gay men are also interested in long-term relationships. However, they are less likely than lesbians to be sexually exclusive, and there is less consensus among them about the importance of sexual exclusiveness to their sense of relationship satisfaction (Deenen, Gijs, & van Naerssen, 1994; Kitzinger & Coyle, 1995). In comparison to lesbian relationships, gay men often find partners in the context of a more active, competitive social scene that involves multiple short-term relationships. In comparison to men in heterosexual couples, gay men are more likely to be emotionally intimate. In the practical matters of household work, gay couples are more likely than heterosexual couples to divide tasks so that each partner does an equal number (Peplau & Beals, 2004). Gay couples report higher levels of closeness and flexibility than do heterosexual couples. Moreover, the combination of flexibility and closeness is strongly associated with couple satisfaction (Kurdek, 2006b).

Many of the same factors are associated with relationship quality across all types of couples: valuing security, permanence, and closeness; expressiveness; perceived rewards for being in the relationship; trust in the partner; good problem-solving and conflict resolution skills; egalitarian decision making; openness to the expression of differences; and perceived social support (Kurdek, 2006b; Peplau & Fingerhut, 2007). Factors that are likely to lead to the dissolution of a gay or lesbian couple are a lack of investment in the relationship, a decline in expressions of positive affect and emotional support, an increase in conflicts, and an increased desire for personal autonomy. Interdependence sustains the relationships, and power inequalities disrupt them.

Given the heteronormative social context, one may ask about factors that support stability in same-sex relationships. From an attachment perspective, it is conceivable that exposure to stressors and threats associated with community prejudice and social rejection strengthen the couple's commitment to one another, and activate their efforts to seek security and safety in one another. From an identity perspective, we can expect that gay and lesbian couples have given extensive thought to the challenges they are

Abe and Craig are a perfect match. Having found each other by chance, they have formed a loving bond that will sustain them for a lifetime.

likely to face as a couple and that they form their relationship with extensive work already done on the expectations they have for one another as committed partners.

Adjustment During the Early Years of Marriage

What are the defining characteristics of a high-quality relationship and how are they sustained during the early years of marriage? Two different theories have been advanced by family scientists. One view, sometimes referred to as the **communal norm**, is that each person should pay close attention to the partner's needs and act in ways that will support the partner's welfare. In a communal relationship, each partner tries to meet the needs of the other within reason, without regard for or without keeping track of what has been received in return. Couples that are characterized as flexibly supportive are likely to view their relationship as positive and satisfying.

A second view, sometimes referred to as the **exchange norm**, is that each person expects to satisfy the needs of the partner and to have needs met in about the same amount. The exchange norm includes a sense of obligation so that what one receives from the partner should be returned in similar value. Partners keep track of the benefits given or received, so that there is a continuous sense of equity or balance in the relationship. Couples who perceive that what is given is equal to what is received will view their relationship as positive and satisfying (Clark & Lamay, 2010).

In a study of couples prior to their weddings and 2 years after they were married, most couples thought that the communal norm was ideal and preferable to the exchange norm. Over time, the couples that relied more on the exchange norm were also less satisfied in their relationship. Individuals who were characterized by an anxious or avoidant attachment became increasingly reliant on the exchange norm 2 years into their marriage as compared to individuals who were characterized by a secure attachment. Even though they viewed the communal norm as ideal, those who had an anxious or avoidant attachment had difficulty establishing a communal, mutually beneficial supportive relationship. The communal norm depends more on trust and reciprocity as compared to the exchange norm that reflects some doubt about the partner's ability to care for and respond to one's needs (Clark, Lemay, Graham, Pataki, & Finkel, 2010). People who have an insecure attachment are likely to be mistrustful of the good intentions of their partner. As a result, they pay very close attention to the value of what they are receiving from their partner in relation to what they give to the partner. This preoccupation with a fair exchange seems to be associated with more marital conflict and lower levels of marital happiness.

Mutual Adaptation. Once the choice has been made and the thrill of courtship has passed, the first few years of a committed relationship involve a process of mutual adaptation. Couples who idealize one another and who see each other in a possibly unrealistically positive light are less likely to experience declines in marital satisfaction and feelings of love as they make their way through these early years (Miller, Niehuis, & Huston, 2006). The first few years of marriage can be extremely difficult, particularly because the couple does not anticipate the strains. The partners may be distressed to find their home becomes riddled with the tensions that are a normal part of carving out a life together. In one study of 1,000 newlywed husbands and wives, problems appear for many couples in the first few months of marriage. Results revealed that 8 percent of newlyweds scored in the distressed range on measures of marital satisfaction and 14 percent scored in the distressed range on measures of marital adjustment after the first few months of wedlock. For both husbands and wives, the most problematic areas in the early months of marriage were balancing employment and marriage and debt brought into marriage (Schramm, Marshall, Harris, & Lee, 2005).

There are many additional sources of tension in a new marriage. If the partners do not have similar religious, educational, or social class backgrounds, they will have to compromise on many value decisions. Assuming a shared value orientation, certain lifestyle decisions can generate tension. The couple must establish a mutually satisfying sexual relationship. They must work out an agreement about spending and saving money. They must also respond to each other's sleep patterns, food preferences, work patterns, and toilet habits. The couple may find the demands of their parents and in-laws to be an additional source of conflict. Often, it is the number of demands rather than any single one that makes the adjustment process so difficult.

As part of the adjustment to marriage, the partners must achieve a sense of psychological commitment to each other. The marriage ceremony is intended to make that commitment public and binding. It is safe to say that most people probably do not fully accept the reality of their marriage vows until they have tested the relationship. Each partner is likely to put strain on the relationship to see how strong it really is. The question of trust may be posed as, "Will you still love me even if I do…?" or, "Am I still free to do what I did before we were married?" Every marriage relationship is different. The partners must discover the limits of their particular relationship, but both partners must feel that they still have some freedom within these limits. They must also believe that the limits are balanced by the love, respect, and support they gain in return. As each test is successfully passed, the partners grow closer. They trust each other more and become increasingly sensitive to each other's feelings. Eventually, the tests diminish in number as the question of trust is resolved. In the study of newlyweds mentioned previously, the factors that worked to protect the marriages included respect, appreciation, commitment, mutual affection, and trust (Schramm et al., 2005).

Communication and Marital Adjustment. Intimacy and a high level of satisfaction require effective communication and the capacity to cope effectively with conflict. Happy couples enjoy being together. They start out their marriages being very much in love, and they view one another as responsive. They value the companionship aspects of their marriage, such as spending time together with friends or having dinner together. The causal nature of this relationship is not fully understood. One might assume that happy couples choose to spend more time together, but it may also be that couples who have opportunities to spend more time together come to feel more positive about their marriage as a result.

High levels of *disclosure* and *disclosure reciprocity* (i.e., you tell a person what you are thinking about, and that person tells you what she is thinking about) are associated with greater relationship satisfaction among marital partners (Finkenaure, Engles, Branje, & Meeus, 2004; Lippert & Prager, 2001). Self-disclosure and partner disclosure both contribute to high levels of intimacy as well as relationship satisfaction. Perceptions of responsiveness from one's spouse also contribute to daily feelings of intimacy. It is likely that the positive impact of self-disclosure and partner disclosure in strengthening intimacy and satisfaction is accompanied by simultaneous increases in perceived partner responsiveness (Laurenceau, Barrett, & Rovine, 2005). The sense of intimacy involves sharing an open, tender relationship with another person. Emotional expressiveness, especially by husbands, and a lack of ambivalence about expressing one's feelings are important elements in this communication process. In contrast, declines in affectionate and pleasurable interactions, lack of intimacy, and increases in ambivalence about the union predict a high probability of divorce (Huston et al., 2001).

Approaches to Marital Conflict. In contrast to factors such as self-disclosure, partner disclosure, and a sense of partner responsiveness, which predict marital satisfaction, negative interactions and conflict are associated with marital distress. Conflict can be a product of the interaction of two well-developed identities, each with a distinct temperament, values, and goals. Conflict can result from the simple day-to-day need to make decisions that the couple has never made before. It can be a reflection of one or both partners' personalities, a tendency toward irritability, mistrust, or an aggressive temperament. It can be a product of disillusionment, as one or both partners perceive that the relationship fails to meet critical expectations. Much of the research on marital distress points to differences in power between the partners, especially differences in the control of resources and ongoing disagreements about the allocation of resources as an underlying source of **marital conflict**. Whatever the source, marital stability and satisfaction are closely tied to how couples manage conflict (Caughlin & Huston, 2006).

Three dimensions of conflict seem especially important in differentiating happy and distressed marital relationships. First, instances of **negative communication**—especially nonverbal negative expressions and hostile put-downs—are more frequent in distressed than in happy couples, even in the first few years of married life.

Second, distressed couples show a pattern of **coercive escalation**—a style of interaction in which the probability that a negative remark will be followed by another negative remark increases as the chain of communication gets longer and longer. This pattern has been observed at the behavioral level by coding the verbal and nonverbal characteristics of an interaction and at the physiological level by monitoring heart rate, blood pressure, and release of stress hormones during communication. As the communication becomes increasingly negative, the partners become so physiologically disorganized that they lose access to their more rational ego functions. Over repeated instances, they become sensitive to this physiological state, reaching it sooner. In comparison, happy couples become more effective in soothing each other and in finding ways of preventing conflicts (Driver, Tabares, Shapiro, & Gottman, 2012).

Third, distressed couples have different perceptions of the approach that their partners are taking to resolve a conflict. For example, one partner may think that he is acting in a constructive way to find a solution, but the other partner may view the behavior as patronizing or minimizing the importance of the

SuperStock

To sustain a marriage, the partners must be able to interact even during periods of conflict. Withdrawal, rejection, and distancing are common reactions to conflict. These strategies may be effective during a brief cooling-off period, but they do not replace direct communication for exploring or resolving differences.

issue. **Congruence** between the partners in how they think they and their partners are approaching the resolution of conflict is significantly related to marital satisfaction, whereas **lack of congruence** is significantly related to marital dissatisfaction and distress (Acitelli, Douvan, & Veroff, 1997).

In an analysis of effective problem solving among newly married couples, partners were asked to identify the areas where they had their most significant disagreements (Tallman & Hsiao, 2004). The four most common issues were money, who does what around the house, communication, and time spent with the spouse (p. 177). The premise of the study was that couples who were able to resolve problems so that both partners were satisfied with the outcome would experience greater levels of marital satisfaction. Another assumption was that both trust in one another and cooperative approaches to problem solving were needed in order to come to mutually satisfying solutions. Over time, the couples who were able to use cooperative problem-solving strategies had greater marital satisfaction, which in turn contributed to improved cooperative behavior in subsequent problem-solving efforts. Moreover, those couples who exhibited cooperative, mutually respectful problem solving were able to maintain their relationship quality in the face of economic distress.

Communication Styles of Men and Women in Marriage.

One hypothesis to account for difficulties in adjustment during the early years of marriage is that men and women have different communication styles, resulting in problems in conflict resolution and emotional closeness. This idea has mixed empirical support. In many ways, men and women are alike. For example, both perceive the value of emotional skills in promoting and sustaining friendships and romantic relationships. They both expect close friends—and especially romantic partners—to have the ability to encourage, soothe, reassure, and validate one another (Burleson, Kunkel, Samter, & Werking, 1996). When faced with upsetting problems, both women and men are most likely to offer suggestions for how to solve the problem or to take some action, rather than simply empathize and identify with the person's problem (Goldsmith & Dun, 1997).

When asked about their preferred mode or style of interaction as a married couple, husbands and wives both prefer interactions that are **contactful**—that is, open to the other person's point of view—and that also clearly express the speaker's own position. They least prefer **controlling interactions**, in which one person expresses her point of view and does not take the other person's point of view into consideration (Hawkins, Weisberg, & Ray, 1980). These similarities suggest that men and women approach the process of establishing intimate relationships with many common skills and values. In constructive conflict resolution, partners are able to support their own position while engaging in interactions that show concern for the other person and for preserving a positive relationship. Both partners are able to disagree while preserving a good level of accuracy about the conflict; they don't exaggerate or overstate one another's position, or claim to know what the other person thinks without confirming their opinion by checking back with the other person (Feeney, 2008).

Couples' communication in conflicts is associated with, and predictive of, marital satisfaction and stability (Noller & Feeney, 2002; Weiss & Heyman, 1997). One pattern of communication that has been documented in the marital interaction literature is the **demand-withdraw pattern**, in which one member (the demander) nags, criticizes, and makes demands of the other to change, while the partner (the withdrawer) avoids confrontation, becomes silent, and withdraws. The demand-withdraw pattern has been found to be consistently associated with relationship dissatisfaction (Eldridge & Christensen, 2002). Further, research has demonstrated that the demand-withdraw pattern is associated with several central aspects of marriage, such as power differences and violence, differences in desire for closeness and independence, femininity and masculinity, gender roles, and division of labor (Eldridge & Christensen, 2002; Sagrestano, Heavey, & Christensen, 1999). The demand-withdraw pattern occurs most often in distressed marriages. The pattern is also extremely resistant to change in these relationships (Baucom et al., 2011; Eldridge et al., 2007).

Although both men and women can be in either role, women are more often in the demanding role and men more often in the withdrawing role. These gender distinctions have been observed in a variety of samples, including dating couples, cohabiting couples, married couples, clinic couples seeking therapy, violent couples, and divorcing couples (Eldridge & Christensen, 2002). The demand-withdraw pattern increases with the length of the marriage.

Some differences in the ways men and women approach communication have implications for the quality of an intimate relationship. The socialization of both sexes in U.S. culture is still sufficiently distinct to result in differences in expectations and competencies. For example, when faced with a problem, men are more likely to want to deny it or to spend time analyzing and defining it in comparison with women (Goldsmith & Dun, 1997). Men tend to value the skills of being a good conversationalist or storyteller and being able to laugh and joke as well as to argue and defend a position somewhat more than do women (Burleson et al., 1996). They tend to be more ambivalent than women about expressing emotions and withdraw to avoid escalating conflict. Women, on the other hand, tend to want to talk things out so that everyone feels comfortable with the situation. In conflicts, these styles can become incompatible, especially if the woman is trying to reach consensus and the man withdraws. In general, women expect and desire a degree of closeness that is often not reciprocated. Men, on the other hand, are more likely to be satisfied with the degree of intimacy that they find in marriage and have fewer expectations of or less desire for greater closeness (Dindia & Allen, 1992).

Adjustment in Dual-Earner Marriages.

One of the greatest changes in U.S. families in the second half of the 20th century was the increase in the number of married women who were employed. It is normative for married women, including those with young children, to be in the labor market. The percentage of employed, married women whose husbands are present was 32 percent in 1960 and 56 percent in 2012. The number of women with young children who work outside the home has also grown substantially. In 2012, 60 percent of married women with children under 6 years of age were in the labor force, compared with 39 percent in 1960 (U.S. Bureau of Labor Statistics, 2013d). Rather than drop out of the labor force and return to work after their children are grown, the majority of women now remain in the labor force throughout the early years of parenthood.

There is no question that the involvement of both partners in the labor market requires the couple to arrive at a satisfactory approach to **work/life balance**. The partners' career ambitions and specific job demands need to be coordinated, and considered in the context of the couple's needs for time together, management of home and family life, and individual needs for fitness, leisure, and time with friends and family. Uncertainty about the expectations and behaviors of the spousal roles must be worked out between the partners. Sometimes, this uncertainty helps to produce greater intimacy by generating interactions that lead to greater self-disclosure by each partner. Personal preferences and habits must be examined if the partners are to arrive at a mutually satisfying division of labor. Sometimes, however, this process is threatening. The partners may not really be aware of their expectations of themselves or of the other person until they are married and faced with these work/family life challenges.

A potential area of conflict for dual-earner couples is the relative balance of power and demands for household labor for the two partners. In the traditional male-breadwinner, female-homemaker family model, the husband has more power as a result of his access to financial resources and participates little in the low-status household tasks. The wife, in contrast, has little power and carries the majority of responsibility for the household tasks. As women have entered the labor market, their access to financial resources has increased. To the extent that their husbands also help in sharing the household tasks, women's well-being and mental health improve.

For men, especially in families where there is a relatively high family income, as their wives' income matches or surpasses their own and they have to take on a greater role in domestic tasks, their well-being declines and their mental health suffers. This is true primarily for men who have traditional views about the importance of men as breadwinners (Brennan, Barnett, & Gareis, 2001). Men who feel demeaned or threatened by demands to participate in household labor are likely to experience depressive symptoms. These reactions are similar to the reactions that women have when they try to carry the full responsibility of household tasks while also participating in the labor market. Finding the balance of power and of household responsibilities that preserves mutual respect and support is a major challenge in the early years of the marriage and has to be fine-tuned and renegotiated throughout the marriage.

In contemporary U.S. society, there are a number of benefits for couples when husbands and wives have multiple roles that include marriage, career, and parenting (Barnett & Hyde, 2001). Four benefits are summarized here.

1. Involvement in multiple roles means that both partners are likely to be more fully integrated into meaningful social support systems.
2. Participation of both partners in the labor force increases financial resources and buffers the couple against fluctuations in each person's job situation.
3. Success in one role can buffer each person against negative experiences in other roles. For example, negative work experiences can be offset by marital happiness and the centrality of parenting.
4. Involvement in similar roles provides husbands and wives with a shared frame of reference. Thus, partners are more likely to appreciate one another's point of view and to empathize with each other's struggles and accomplishments.

However, there are limits to the benefits of the dual-earner arrangement. The advantages of the dual-earner, multiple- role lifestyle can be offset when one or both partners experience role overload—for example, if the care of an ill parent is added to an already full basket of responsibilities. The quality of the roles can undermine the benefits, as when a person is in a terrible job with inadequate wages and oppressive work conditions. Chronic stressors at home that create feelings of overload or lack of control can make the daily hassles of home or work life seem even worse. These ongoing stressors, which result in frequent but unpredictable demands, can cause psychological distress in the individual and disrupt relationship satisfaction (Serido, Almeida, & Wetherington, 2004). Multiple roles can be disruptive if a partner holds traditional gender-role values that are in conflict with the enactment of multiple roles. Finally, couples may find that their actual work schedules do not fit well together, leaving too little time to be together or too little control over their non-work life (Barnett, Brennan, & Gareis, 1999).

Roughly 100 years of social science research has established that satisfaction in the relationship of marriage contributes significantly to psychological well-being, including a greater sense of social integration and protection from other life stressors. For most adults, happiness in life depends more on having a satisfying marriage than on any other domain of adult life, including work, friendships, hobbies, and community activities. Longitudinal studies of adults who either remained single or got married and remained married over a 7-year period found that those who were married had higher levels of well-being and fewer mental health problems (Horwitz, White, & Howell-White, 1996; Williams, 2003). The benefits of being married for mental health and life satisfaction accrue primarily in the context of happy marriages where the partners describe their relationship as one in which their spouse makes them feel valued and cared for (Williams, 2003).

FURTHER REFLECTION: *Review the developmental tasks and psychosocial crises of earlier life stages, from infancy through later adolescence. What are some psychosocial resources from earlier stages that would contribute to a person's ability to form and sustain an intimate relationship in early adulthood? What are some areas of vulnerability that might prevent the formation of these relationships?*

What characteristics are important to you in a long-term romantic partner? On what dimensions is homogamy important to you in the choice of a mate?

Childbearing

OBJECTIVE 3 Describe the factors associated with the decision to have children, and evaluate the impact of childbearing on intimate relationships.

During early adulthood, decisions about reproduction and childbearing are confronted many times. Young adults make choices to delay parenting, have an abortion, have a child, wait before having another child, or stop having children altogether. Many couples undergo difficult and expensive procedures to conceive a child. Others who are unable to conceive decide to adopt children. Some adults become foster parents, whether or not they have children of their own. Even unplanned pregnancies are products of some kind of decision making—whether to have sexual relations knowing that pregnancy is possible, decisions about contraception, and decisions about whether to abort the pregnancy or to carry the child to term.

In all of these decisions, many powerful themes are reflected: one's sense of fulfilling a masculine or feminine life purpose by having children; one's childhood socialization and identification with parental figures; religious beliefs about sexuality, contraception, or abortion; and ideas about carrying on a family's ancestry and traditions. Reproduction is the means by which the species perpetuates itself. As people reflect on their lives, the birth of their children is commonly recalled as a life-story high point (McAdams & Bowman, 2001). Regardless of the decisions one reaches, this issue cannot help but heighten the sense that the decisions of adulthood make a difference (Lydon, Dunkel-Schetter, Cohan, & Pierce, 1996).

Fertility Rate

The average number of births required for the natural replacement of a population is calculated by assuming that for every adult woman in a population, a female child must be born who will reach reproductive maturity and have children. Because slightly more male than female children are born and because not all children reach childbearing age, the estimate for a population replacement reproductive rate is 2.1 births per adult woman (Bachu & O'Connell, 2001).

The **fertility rate** in the United States has fluctuated from the late 1950s, when the rate was 3.5 births per woman, to a low of 1.8 in the 1970s. In 2012, the rate was 1.989, slightly below the replacement estimate. Fertility rates in the United States vary by race, ethnicity, and socioeconomic status. Latinas have the highest fertility rate; Asian or Pacific Islanders have the lowest. Women who have graduated from high school or less have a higher fertility rate than women who graduated from college. Women who are not in the labor force have a higher fertility rate than those in the labor force. Women whose family income is below 200 percent of the poverty level have a higher fertility rate than those above 200 percent of the poverty level (Monte and Ellis, 2014).

Decisions About Childbearing

Decisions about **childbearing** are made in the context of other personal and family goals and commitments. Factors such as religious beliefs, career aspirations, ideals about family life, and social expectations in the family and culture all contribute to a couple's commitment to bearing children and the timing of first and subsequent pregnancies. Cultures differ in the norms and expectations they convey about the value of having children and the appropriate timing and frequency of pregnancies (see the **Human Development and Diversity** box The Reproductive Career of the Gusii).

Attitudes about the desire to have children and the importance of having children to personal happiness have changed over time. Thornton and Young-DeMarco (2001) compared responses from men and women as well as adolescents from five different national U.S. samples. Data were collected in the 1960s, 1970s, 1980s, and 1990s, with the most recent data coming from adolescents surveyed in 1997–1998. Over time, two themes emerged. First, in the more recent decades, people viewed childbearing within marriage as more of an option than an obligation. From the 1960s to the 1990s, respondents increasingly disagreed with the idea that all married couples who can have children ought to have children. This concept was positively endorsed by 84 percent of mothers in 1962, but by only 41 percent of mothers and 22 percent of their adult daughters in 1993. Similarly, in the 1980s and 1990s, the majority of people disagreed with the idea that having children is the main reason for getting married, or that people who did not have children led meaningless lives. Nonetheless, the study reported a steady endorsement of the value of parenting among young people. The majority of high school seniors who were surveyed from the mid-1970s through the late 1990s agreed that fatherhood and motherhood are among the most fulfilling experiences of adulthood; roughly 60% of these students (both male and female) said they were likely to want to have children.

Pursuing this line of inquiry, a recent national survey compared attitudes about the importance and the contexts for childbearing among men and women ages 15 to 44 in samples from 2006–2010 and 2011–2013. In 2011–2013, only a small percentage of women (6.4 percent) and men (9.4 percent) agreed with the statement that people can't be really happy unless they have children. However, a majority of men and women agreed that it is okay to have and raise children when the parents are living together and not married, and that it is okay for an unmarried woman to have and raise a child. Thus, current attitudes appear to be more accepting of a variety of contexts for childbearing and childrearing, while at the same time endorsing the view that childbearing is not an essential condition for life satisfaction (Daugherty & Copen, 2016).

Although the majority of married couples intend to have children, the timing of their entry into parenthood varies. From 1975 to 2010, the age of entry into parenthood has been getting older. Whereas the years from 20 to 29 are still the most typical age for having children, far fewer women have babies in their teens, and many more have babies in their 30s and beyond (see FIGURE 11.4 ▶). Both the social and biological clocks come into play in this decision. The social clock refers to expectations from family, friends, and coworkers about the optimal time to start a family. In recent years, many couples have decided to postpone childbearing. This decision is related to other developmental tasks of adult life and needs to be understood in the context of competing goals, including education, career aspirations, housing, and a desire to experience intimacy with a partner prior to having children. Dual earner couples have to consider the effect of children on their family income. They may try to anticipate the best timing for childbearing in relation to job security or career advancement. Some couples set certain material goals for themselves as a prerequisite to having children. For example, they may decide to wait until they can buy a home, establish a certain amount of

HUMAN DEVELOPMENT AND DIVERSITY

The Reproductive Career of the Gusii

Robert LeVine (1980) described the patterns of adulthood among the Gusii, a tribe living in the Kisii highlands of western Kenya, about 50 miles south of the equator. The Gusii lived in a well-protected, fertile area where they were able to expand their communities and grow their crops. LeVine characterized their adult life course as being composed of three interdependent spheres: reproductive, economic, and spiritual. His description of the reproductive career illustrates how personal and societal expectations influence the childbearing decisions of young adults.

> The reproductive career seems to be the most salient for both sexes. Its goal is to become the ancestor of a maximally expanding genealogy. For women, this means to have children as frequently between marriage and menopause as is consistent with child health, which the Gusii believe to be every 2 years. A man who fails to impregnate his wife that often will be publicly accused by her of neglect. The woman must have at least one son to take care of her in her old age and whose wives work with her; to have nothing but daughters (who move away at marriage) is second only to barrenness as a disaster. If her husband dies, it is her right as well as her obligation to have a leviratic husband to impregnate her regularly so she will continue to bear children "for the dead man."
>
> For men, the goal means not only maximizing his wife's offspring but also taking additional wives as he can afford them and so appending their reproductive careers to his. If a man has been a monogamist, he might take a younger second wife when his first wife reaches menopause, for that would extend his reproductive career by a decade or more. The reproductive career as I see it, however, is not limited to the individual's own procreation but includes that of his or her offspring. Grandchildren are as fervently desired as one's own children and, not incidentally, play an essential role in the burial of the grandparents. (LeVine, 1980, p. 94)

The value placed on having children, the practice of child spacing, and the practice of extending the father's reproductive career by adding a second, younger wife all contribute to the high fertility rate of the Gussi (LeVine et al., 1996). In 2011, the fertility rate in Kenya was 4.7 births per woman. However, current conditions threaten the reproductive career of the Gusii. The mortality rate for children under 5 years old is 73/1,000 live births in Kenya (Countdown, 2013). The following issues impact the survival of children under the age of 5:

- Maternal mortality. Approximately 360 Kenyan women die in every 100,000 live births. Without their mothers, infants are at great risk for survival.
- Only 44 percent of women are attended by skilled health professionals at childbirth. There is a lack of comprehensive obstetrics, neonatal care services, and emergency obstetrics in many hospitals, particularity in rural areas, and there are delivery complications arising from many deliveries done outside health care facilities and not supervised by skilled health workers.
- HIV/AIDS and its related opportunistic infections—increasing HIV infection rates among pregnant mothers and mother to infant transmission. Roughly one third of pregnant women who are HIV positive lack access to Preventing Mother to Child Transmission (PMTCT) services.
- Hunger and the resultant protein-energy malnutrition (PEM) among children. Roughly 16 percent of children under age 5 are significantly underweight, and 35 percent are stunted, meaning that their overall growth in height is well below average.
- Widespread incidences of preventable diseases due in part to a lack of immunization, poor water quality, and lack of access to antibiotics. Only 50 percent of children diagnosed with pneumonia receive antibiotics. Malaria, diarrhea, and acute respiratory infections, which mainly impact children, currently contribute to about 50 percent of all reported morbidity and about 25 percent of all reported deaths.
- Literacy levels and low mothers' education levels in many parts of the country. Children of mothers with little or no education have the largest risk of mortality.
- Inadequate access to sustainable clean water sources and sanitation facilities.

These factors illustrate the potential disruptive forces of modernization on traditional cultural systems and practices.

Critical Thinking Questions

1. Analyze the differences in the orientation toward childbearing between the Gusii and young adults in the United States.
2. Evaluate the likely impact of greater contact with the more industrialized, commercial world on the Gusii and their reproductive values and behaviors.
3. How might the goal of becoming an ancestor of an expanded genealogy affect men and women's health and reproductive practices for the Gusii? For your own family?
4. Describe how taking a second, younger wife in order to continue a man's reproductive career may be perceived by his first wife. Speculate about a cultural equivalent to this practice in contemporary U.S. culture.

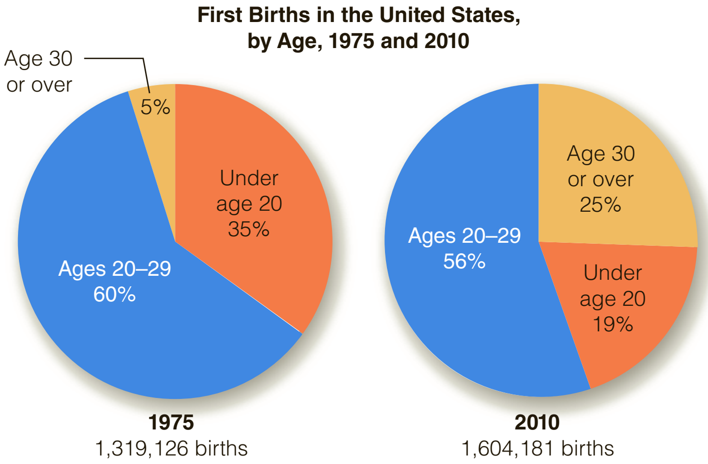

FIGURE 11.4 ▶ AGE AT FIRST CHILDBEARING, 1975 AND 2010

Source: CDC/NCHS, National Vital Statistics System

savings, or travel together before they have children. Given the high divorce rate, couples are likely to want to feel confident that their relationship is strong before deciding to have children.

Delayed entry into parenthood has typically been studied in relation to the characteristics of the woman. It has been found to be related to a woman's level of education, her career commitment, and the family's income.

> Zine Magubane (age 32) and her husband, Patrick McCabe, married in June. She's got a tenure-track university teaching job; he's a sports agent who travels constantly. They want to wait at least a year before beginning a family "to get a little more stability," says Magubane, whose mother delivered her at 36. Today she works hard to stay healthy, knowing she'll be an older mom. (Kalb, 2001, p. 43)

In a study of the timing of entry into fatherhood, men who were characterized as late-entry fathers (30 years old or older) were more involved with their children and had more positive feelings about them than did the on-time or early fathers (Cooney, Pedersen, Indelicato, & Palkovitz, 1993). Older fathers may feel that they have less conflict between their commitments to work and to family. They may feel that they have already demonstrated their ability to succeed in the breadwinner role and, therefore, can approach parenthood with more confidence and a greater sense of self-efficacy. Older fathers may have more emotional resources to bring to their marriage and their parenting relationship.

Decisions to postpone childbearing are also constrained by the *biological clock,* the closing of reproductive capacity for women and increasing risks of infertility and birth anomalies with age. After age 30, women's fertility rates decline, and by age 40, miscarriages increase. Reproductive technologies that involve fertilizing a woman's own eggs decrease from 40 percent effectiveness for women in their late 20s to less than 10 percent for women in their 40s. However, new ideas are being introduced that may push back these constraints, such as transferring the cell nucleus from an older woman's egg, transplanting it into the cytoplasm of a younger woman's egg, and implanting the new egg into the older mother so that she can experience pregnancy and childbirth (Kalb, 2001).

The patterns discussed above may lead one to believe that couples are making very deliberate, strategic decisions about the timing for their childbearing. However, in 2011, 45 percent of the 6.1 million pregnancies in the United States were unintended, meaning that the pregnancy was mistimed (the woman did not intend to get pregnant at that time) or unwanted (the woman did not want to be pregnant at all). Later adolescents, ages 20 to 24 have the highest rate of unintended pregnancies of any age group (Guttmacher Institute, 2016c). Moreover, among women who have had one unintended child, about one third have another unintended birth (Wildsmith, Guzzo, & Hayford, 2010).

In addition to one's intentions about childbearing, certain other experiences feed into fertility decisions. For example, characteristics of the firstborn child influence a couple's decision about having another child. When the firstborn child has a sociable temperament, has relatively few behavioral problems, and shows a readiness and eagerness for learning, families are more

This couple's affection for and commitment to each other is expanding to include love for their unborn child. How might the quality of the parents' relationship influence the experience of pregnancy?

likely to be enthusiastic about having another child (Jokela, 2010). Sometimes the conditions leading up to pregnancy, such as sexual abuse or unusually difficult experiences of pregnancy, result in a reluctance to have additional children (Sperlich & Seng, 2008). Social policies, such as the one-child policy in China, or the welfare policy in the United States, which emphasizes labor force participation for mothers of young children, can have an impact on childbearing decisions.

Adjustment During Pregnancy and Childbearing

Although most women are healthy and happy about being pregnant, there is growing concern about how to treat mood disorders among women during pregnancy and after childbirth. Numerous studies document the disruptive impact of maternal depression on the infant's cognitive and emotional development and the associated mother–infant relationship (Pearson et al., 2010). Some women are chronically depressed prior to pregnancy and are being treated with psychotropic drugs. Other women become anxious or depressed during pregnancy. The challenge is whether to continue the use of these therapeutic drugs, weighing the risks of potential harm to the fetus and the risks of untreated or increased depressive symptoms for the pregnant woman (Cohen et al., 2010). Approximately 13 percent of women experience mild to moderate depression in the first 3 months following childbirth (Bick & Howard, 2010). Many cases of depression go undiagnosed and untreated, resulting in maternal distress, negative affect, reduced sensitivity to the infant's signals, and disengagement from the mothering role.

The Dual Roles of Intimate Partner and Parent

In contrast to the elation that usually accompanies the anticipation of and preparation for the newborn, the arrival of the first child often brings a period of stress to the relationship (Newman, 2000). Belsky and Rovine (1990) found clear evidence of individual differences in how couples adapted to the transition to parenthood. In their longitudinal study of 128 families, they observed four patterns of change in the assessment of marital quality: (1) Some couples showed a rapid decline in marital quality after the first baby was born. (2) Others showed a slow, steady decline. (3) A third group showed no significant change. (4) A fourth group showed slight increases in marital quality. These findings caution us not to overgeneralize group trends to individual cases.

The quality of marital adjustment during the transition to parenthood is closely related to marital quality before the child was born (Heinicke, 2002). Couples who are in close, confiding, satisfying marriages before their children are born tend to show higher levels of marital adjustment 3 months after childbirth than do couples in conflictual marriages. However, many couples experience increased conflict after the birth of their first child. If the relationship was negative and the partners had high levels of conflict prior to the baby's birth, these difficulties are likely to increase (Crohan, 1996).

In some couples, conflict escalates to physical violence. An estimated 4 percent to 8 percent of pregnant women experience violence from their intimate partner during the pregnancy. The risks of intimate partner violence are greater in low-income households, especially in communities where people feel trapped in a life of poverty and disorganization. Negative consequences associated with this violence include miscarriages, abortions, injury or death to the pregnant woman, and continued abuse after the child is born (Li et al., 2010; Silverman et al., 2010). Several characteristics of the partner relationship, especially shared involvement of the partners in household tasks and commitment to the relationship, reduce the likelihood of such violence (Bradley & Gottman, 2012).

In an attempt to understand how marital satisfaction changes during the transition to parenthood, researchers compared marital activities and evaluations of the marriage by parents and nonparents who had been married the same number of years (Huston & Vangelisti, 1995; MacDermid, Huston, & McHale, 1990). Over the first 3 years of marriage, couples' ratings of love and satisfaction declined somewhat. There were no differences in the magnitude of the decline for parents and nonparents. Having children did not account for a greater drop in love or satisfaction than occurred as a result of adjusting to marriage in general. This is an important observation that provides new insight into much of the earlier research on marital satisfaction and the transition to parenthood (Holmes, Huston, Vangelisti, & Guinn, 2013).

Having children did have an impact on **marital companionship**. The percentage of leisure activities shared by the husband and wife dropped sharply after the baby was born, but it declined only slightly for the couples without children. During the third year of marriage, parents had a greater number of shared activities per day than nonparents, but few when the child was not present. FIGURE 11.5 ▶ shows the number of minutes of joint leisure time per day without the child for two groups of parents in comparison with joint leisure time for nonparents in the first, second, and third years of marriage. After the birth of their child, couples have only about one third as many minutes together alone as they had when they were childless. The nature of companionship in marriage changes to incorporate a baby and therefore may become less intimate.

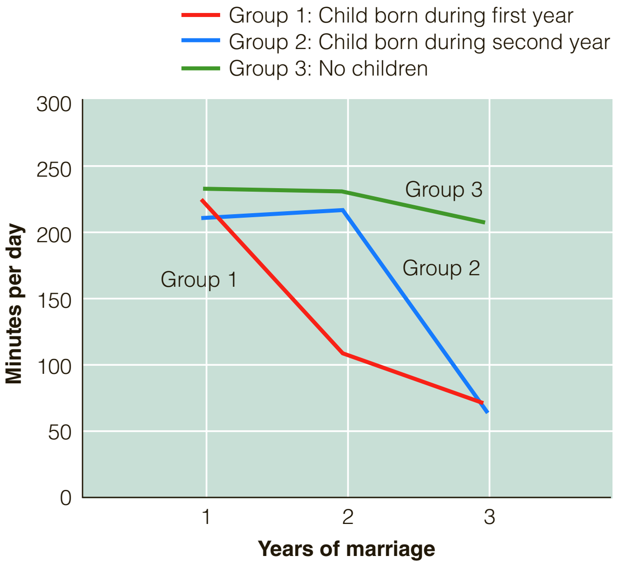

FIGURE 11.5 ▶ DURATION OF JOINT HUSBAND-WIFE LEISURE WITHOUT CHILD FOR PARENTS AND NONPARENTS

Source: Based on MacDermid, Huston, and McHale, 1990.

For most couples, coping with the early months of childrearing strengthens the bond between the partners. The partners begin to respect each other's competence in caring for their child. They also begin to conceptualize their roles as parents and to view the increasing complexity of their family structure as a challenge rather than a burden. The new baby adds a degree of energy to the family through expressions of satisfaction, pleasure, and affection.

As the roles of mother and father are added to the adults' repertoire of role relationships, adults face new challenges in balancing their work, intimate partner, and parent roles. A variety of factors influence adults' ability to achieve a positive sense of role balance. Access to financial resources helps couples enjoy leisure time and purchase services that can reduce some degree of role strain. When partners are equally highly invested in their parental roles, they are more readily able to make the trade-offs and compromises that parenting requires, including modifying their leisure time to incorporate each other's interests and the presence of their young child. In contrast, when partners have to work long hours, especially on the weekends, or try to pursue individual leisure interests that do not include their partner or child, they may have more difficulty achieving a comfortable sense of role balance (Claxton & Perry-Jenkins, 2008; Marks, Huston, Johnson, & MacDermid, 2001).

The daily demands of the child help the parents define their own roles more realistically. Instead of wondering what parents should do, they are occupied with the actual demands of parenting. Through this experiential learning, young adults formulate their own definitions of parental roles. Assuming that the early experiences are successful and the parents are able to meet their child's needs, they gradually achieve a new level of self-efficacy in the parenting role, gaining new confidence in their ability to provide a nurturing environment for their child.

The process of social attachment and its impact on the infant were discussed in chapter 5 (Infancy). The theme of mutuality as the central process for the establishment of trust was stressed. Mutuality also has an impact on parents. Infants actively engage their parents, evoke unique responses, and, through their differential behaviors, begin to shape parenting behaviors. Infants respond to their parents with shrieks of delight, elaborate smiles, and the active pursuit of them. They are unrestrained in their loving. They mouth, bite, grab, laugh, smile, squeal, and coo in response to pleasure. Through their open demonstrations of affection, infants teach adults about the expression of love and increase their parents' ability to demonstrate it. As parents and children begin to engage in playful interactions, the capacity to establish and maintain reciprocal interactions expands. Children learn how to initiate a play sequence by bringing a toy or making a playful gesture. Parents then learn how to respond by complying to the request for play, sitting down on the floor, bringing out the box of favorite play materials, or tickling and tumbling. As children and parents experience mutual, congruent playful interactions, the bond of affection is strengthened and communication is enhanced (Lindsey, Mize, & Pettit, 1997).

Couples with children find new ways to spend time together that includes their children. Rather than a romantic ski weekend for two, this family romps in the snow and builds a friendly snowman.

Nonmarital Childbearing

In 2014, over 1.6 million babies were born in the United States to women who were not married. Of all births in 2014, 40.2 percent were to unmarried women (CDC, 2016). Within the age range 15 to 44, the birth rate (births per 1,000 unmarried women) was highest among unmarried women ages 25 to 29 (Hamilton et al., 2015). The decision to have children outside of a marriage relationship at this age may be a result of recent divorce or widowhood, a decision reached in the context of a lesbian or a cohabiting relationship, or a decision to start a family without a partner. A substantial number of nonmarital first births are taking place in the context of cohabiting unions. From 2002 to 2011–2013, there has been increasing social acceptance among men and women toward the idea of unmarried women having and raising children (Daughtery & Copen, 2016). The website of Single Mothers by Choice (http://singlemothersbychoice.org) provides some insights into the motivations and resources of women who deliberately choose to have a child without a partner.

Adoption

Adoption is an alternative to childbearing for individuals who want to start a family or expand their family. Data about the total number of adoptions taking place in the United States are difficult to obtain. No single agency is responsible for gathering these data, and adoptions can take place in a variety of contexts. Overall, adoption is relatively rare today. One government report found that in 2012, an estimated 119,514 children were adopted in the United States. This is a decline of 15 percent since 2001 (Child Welfare Information Gateway, 2016).

Adoption can occur between related family members or between unrelated individuals. Roughly half of adoptions involve family members who adopt, for example, when adults with children remarry and their children are adopted by their new partner, when adults adopt the children of siblings who have died, or when grandparents adopt their grandchildren because the adult children are not able to parent. Infertility is the most common reason that adults adopt unrelated children. Other reasons that adults give for adoption include religious or philosophical convictions, for example, a belief that it is more responsible to care for otherwise parentless children than to reproduce, to prevent passing an inheritable diseases (e.g., Tay-Sachs disease), to avoid contributing to perceived overpopulation, and health concerns relating to pregnancy and childbirth.

Over the past 30 years, the context of adoption has changed, resulting in fewer children available for adoption. The fertility rate in the United States has declined, and teen births, which were a source of many adoptive babies, have also declined. Social welfare practices have become increasingly focused on family preservation, emphasizing the importance of keeping children with their birth parents. International adoptions have also decreased. Countries including Vietnam, Guatemala, China, and Russia have taken steps to try to arrange for local adoption rather than sending their children to the United States (Seabrook, 2010).

Within the Child Welfare System, the adoption process is intended to support the best interests of children; however, this is not always easy to assess. Parents may experience some continued feelings of sadness as a result of not having a biologically linked child. This sadness or disappointment might be conveyed to their adoptive child. Adopted children may also experience feelings of loss as they learn of the separation from the birth mother, or in the case of international adoption, as they begin to understand the separation from their cultural heritage (Grotevant, 2009). When children have been in foster care for 2 years or longer, the lack of continuity in the attachment process and harsh or unstimulating conditions of care can have significant negative consequences for children's emotional and cognitive development. Adults who adopt older children or children with special needs and disabilities require additional support in order to provide an appropriate environment. In a review of 36 studies of post-permanency adjustment, both risk and protective factors were identified that were associated with adoption outcomes. Risk factors included caring for a child with special needs, adopting a child that had been in multiple placements or who had experienced a history of abuse or neglect, adoption involving parents who had no prior parenting experience, families that were experiencing their own boundary ambiguity, and families that lacked adequate social support. Protective factors included having adoption preparation, adoptive parents who were married, high levels of openness about the adoption process, and a strong network of social and professional support (Liao, 2016). At present, the preparation and training for adoptive parents to help them address these concerns are not adequately developed (Palacios & Brodzinsky, 2010).

Open adoptions, which are becoming increasingly common, strive to preserve the sense of family origins and connections so that children have a clearer picture of their developmental history as they mature. The success of this openness depends on the willingness of the birth mother to share information, and on the skill of the adoptive parents to incorporate this information into the narrative for the child about how their family was formed (Neil, 2009).

The Decision Not to Have Children

Not all couples choose to have children. In 2014, 15.3 percent of women ages 40 to 44 were childless, twice as many as were childless 30 years ago. Fewer Hispanic women are childless than White non-Hispanic and Black women (U.S. Census, 2015e). Much like attitudes toward remaining single, attitudes toward a lifestyle in which a couple chooses not to have children are becoming more accepting. As discussed earlier, childbearing is increasingly viewed as a choice rather than an obligation. This shift is evidenced in part by a change in the sociological jargon from the term *childless* to the newer term *voluntarily childfree*. The decision not to have children is becoming increasingly common, not only in the United States, but also in other industrialized nations, especially as women's educational attainment, occupational commitments, and income reach new levels (Giles, Shaw, & Morgan, 2009).

Nonetheless, resisting social expectations that married couples ought to bear children requires a high level of personal autonomy and less need for social support from a wide range of reference groups. It may also require a competing positive identity, such as commitment to one's career goals, or a redefinition of gender roles to sustain and validate this decision.

Kelli Cooper (2016) shares her personal thoughts about not having children.

> I believe our purpose is to experience life from our unique perspective, and be happy—not simply reproduce. That is just one of the countless experiences available to us.
>
> But that conditioning runs deep, and I struggled at times. I worried I was "weird" or would regret it. There are some pretty unflattering assumptions about women like me, like we are selfish, cold or emotionally damaged. Harsh.
>
> I do know for certain there was never a time when I felt like I wanted children. I was never really "on the fence" and my journey was more of examining why I felt this way so strongly, and getting comfortable with it.
>
> The moment I truly realized how I felt was while doing some exercise from a book. I was to write down a list of things I wanted most, and then rank them in order of importance.
>
> I remember being really into it, and excitedly writing down all my desires without restraint. There was travel, devoting myself to personal growth, inspiring people to live a better life, being self-employed and living life on my own terms. I had a burning desire to be free. All of these things came to pass, and it's wonderful. And during this exercise, having children **literally** did not enter my mind, not even as a thought I rejected.

The U.S. culture continues to be *pronatalist,* placing a high value on the meaning of parenthood in adult life. Women's childbearing decisions are often influenced by their own mothers' religiosity and their childhood religious teachings (Pearce, 2002). In some ethnic and religious groups, having children is considered a sacred trust. For example, within the Mormon Church, children are highly valued. "Mormon doctrine states that children are the spirit sons and daughters of heavenly parents, and that God holds parents responsible for their stewardship in raising them in righteousness" (Lambert & Thomasson, 1997, p. 90).

Through a pronatalist lens, motherhood is viewed as the symbol of a woman's ultimate identity, regardless of her other talents or accomplishments. Mary Blair-Loy (2001) described a powerful *family devotion schema* among women—a view that the ideal mother should be committed full-time to her children and the well-being of her family. This view is contrasted to the *work devotion schema*, which suggests that an ideal employee should devote all time to the work setting. In comparison to people in many European countries, workers in the United States work longer days, take less vacation, have no paid maternity leave, and have limited access to quality infant care. The tensions between pronatalist cultural values, devotion to the work ideal, and the lack of workplace policies that support parenting result in many women leaving the labor market during their childbearing years or reducing their labor participation to part-time employment (Williams & Cooper, 2004).

FURTHER REFLECTION: *Summarize your views about the importance of having children. How does childbearing fit into your concept of yourself as an adult and your plans for adult life?*

Work

OBJECTIVE 4 Define the concept of work in early adulthood and explore how work stimulates psychosocial development.

Within the life course framework, the occupational career is a major trajectory in each person's life story. Efforts to balance and coordinate work and family life produce some of the greatest challenges of adult life. Work is the primary means of accumulating financial resources. It is the focus of attention for much of the waking day. One's work determines in large part the activities, social relationships, challenges, satisfactions, and hassles or frustrations of daily life. Work is the context in which many adults express their personal identity, experience a sense of personal value, and achieve their social status.

In chapter 10 (Later Adolescence), we discussed the developmental task of career choice, emphasizing the link between career decision making and other aspects of individual identity. Here we focus on adaptation to the world of work where the demands of work present new challenges and opportunities for development.

The concept of work is complex. The following discussion considers a few general characteristics of work and their potential impact on cognitive, social, and emotional development and on one's sense of self in adulthood. It is difficult to be more specific since occupational roles are so varied and each job role places the individual in a somewhat different psychosocial context, with a unique combination of expectations, resources, and strains.

The World of Work

To appreciate the variety of career paths and their impact on daily life, you may want to consult the Bureau of Labor Statistics' *Occupational Outlook Handbook*, which has projections for jobs in hundreds of industries for the period 2014 to 2024 (www.bls.gov/ooh). For each career, the handbook provides information about the training and education needed, earnings, expected job prospects, what workers do on the job, and working conditions.

val lawless/Shutterstock.com

This typewriter was a staple technology of the publishing, secretarial, business and journalism fields. Now it is obsolete.

The nature of the workplace is changing rapidly. Many factors have introduced new levels of uncertainty into the process of choosing a career, finding work, and staying employed. These factors include: the transformation from agricultural to manufacturing to service, computer, and advanced technologies; the increasingly global nature of business; the higher educational standards required for entry into many careers; the expectation that workers will be able to perform across a variety of tasks; and the rapid evolution and extinction of specific types of work brought on by new technologies. Even as advanced technologies are creating new kinds of jobs and careers, automation and robotics are replacing others. Think of the way Amazon and other online services are replacing retail "brick and mortar" stores, or the way self-service kiosks are replacing cashiers. The most common occupations in the United States—retail salesperson, cashier, food and beverage server, and office clerk—may eventually be substantially reduced or replaced through automation (Thompson, 2015). Those who are writing about the future of the workforce suggest that growth areas include robotics, cybersecurity, the commercialization of genetically modified products, mining and application of big data sets, and the impact of digital technologies on money and markets (Ross, 2016). Preparation for these fields obviously begins with advanced courses at the high school level in science and math, continued education at the undergraduate and graduate levels, and ongoing workplace training.

Because economic, technical, and social conditions are changing so rapidly, young adults face two related challenges as they navigate the world of work. First, they cannot expect that strategies or patterns that led to success in the past will necessarily lead to success in the future. Second, they need to be more proactive in designing or inventing an occupational identity that conveys the way their unique education, talents, and experiences are a good fit for the demands of a particular kind of work (Handy, 2001, 2008; Patton & McMahon, 2006).

The early phases of career decision making, presented in Tiedeman's model in chapter 10, focus on self-understanding; career exploration; identifying a good match between personal interests, skills, and values, and particular careers; and learning as much as possible about the specific job opportunities in a career domain. However, because of the wide variety of occupational choices and associated work settings, one can make only limited progress in preparing to enact a specific occupational role during later adolescence. Even though many employers consider educational attainment a selection criterion, they often use it more as an element in determining one's eligibility for the job rather than as a detailed assessment of whether one has the background and skills to perform it. For that reason, many employers emphasize the importance of internships, apprenticeships, and/or course-related field experiences as valued qualifications. What is more, organizations are moving away from large numbers of permanent full-time employees toward more part-time, consulting, and project-based positions.

Most jobs require a period of training for the entry-level employee, which varies from a few weeks in the case of an assembly-line worker to 10 years in the case of a physician. This is the induction phase in Tiedeman's model. Most people do not stay at their first job. A national longitudinal study followed the work experiences of people who were 18 years old in 1978 through age 48. During this period, the average number of jobs they held was 11.7 (Bureau of Labor Statistics, 2015d). A job was defined as a period of uninterrupted employment with the same employer, even if the job responsibilities changed. Most of this job mobility occurred during later adolescence (18 to 24), when the average number of jobs held was 5.5. By the age of 30 to 34, the average number of jobs held was 2.4. Even at the age of 40 to 48, the average number of jobs held was 2.4, suggesting a degree of job mobility over the stages of early and middle adulthood. Job changes do not necessarily imply a complete career change. A person might work for different employers doing the same type of work. The formation of what has been called an attachment to one's career takes most adults a while to establish. Therefore, the training phase is not only about acquiring the specific knowledge and skills necessary to carry out the work, but also about developing the personal, interpersonal, and transferable skills that will be important as one moves around the labor market.

The training period involves a process of socialization of the new worker. During this time, the individual must evaluate the match between personal characteristics and goals and four central components of the work situation: (1) technical skills, (2) authority relations, (3) unique demands and hazards, and (4) interpersonal relations with coworkers. These are the major arenas for new learning in early adulthood. Each of these components might become a source of increasing satisfaction or personal dissatisfaction that might lead to the decision to look for a new position.

Jeneen is just out of engineering school. She is working with a civil engineering firm to explore a career in the building and construction field. Here, she works with Ted, a master engineer with many years of experience on the job. He is teaching her how to read a blueprint and translate the plan into a reality in this partially constructed building. While she explores this field in order to determine if she enjoys this work, the firm observes how well she learns and performs in order to determine whether she should be encouraged to continue in this field.

Technical Skills. Most jobs require a degree of technical expertise, which varies greatly from one occupation to another. The job training phase involves learning new skills. A report from the Organisation for Economic Cooperation and Development summarized the amount of informal training experienced by workers in 35 countries. More than 40 percent of adults reported being involved in some type of informal education or training each year, with a lifetime average of 715 hours of job-related informal education over their career. Workers with more formal education also sought and received more informal job-related education (OECD, 2011). Specific skill training and general technical competence are part of the job demands. The success of individuals in learning and applying new skills determines to some extent whether they will become attached to the occupation. At the same time, the opportunity to learn new skills is part of what permits new workers to advance and seek new employment.

As a result of the recession of 2007–2008, a large number of workers were forced to seek new skills through job retraining in the wake of massive firings and downsizing. Trade Adjustment Assistance is a government program for workers who were laid off as a result of shifting industry to foreign countries and who enroll in new training programs. Since its inception, over 2 million U.S. workers have taken advantage of this program to return to school and learn new skills in fields that have growth potential. Some colleges and universities have made a special effort to reach out to returning adult students to offer retraining to those whose jobs were lost as a result of the economic downturn. For example, Beverly Berndt was laid off from her job as a computer programmer for a cabinet hardware distributor. With help from the Trade Adjustment Assistance act, she went back to school to earn her nursing degree. "I hate to say it, but getting laid off from Belwith was probably the best thing that ever happened to me—getting help from the state for tuition and books, and drawing unemployment—I couldn't have done it without it" (Bauer, 2010).

Authority Relations. Each job role specifies status and decision-making relationships among workers. One aspect of job training is learning which people evaluate one's work, the criteria they use, and the limits of one's autonomy in the job. In today's organizational environment, career ladders are less obvious, and the authority hierarchy may be difficult to identify. Young workers may be assigned to a number of projects with different leaders, they may be asked to take on significant leadership roles early in their careers, and they may need to form interdependent, collaborative teams (Collin & Young, 2000). New workers must attend to both the authority structure and the people who occupy positions in it. They must also assess the channels for decision making and the ways in which they can influence decisions. With respect to the people who occupy positions of authority, new workers must be able to deal with a variety of personalities in positions of higher and lower status. Having a good relationship with one's supervisor is a key element in job satisfaction. The opportunity to form a cooperative relationship with an experienced mentor has been identified as a valued feature of career satisfaction and professional advancement. For early-career phase workers, the immediate supervisor can play a key role by recognizing the talents of a younger worker, encouraging a worker to apply for more training, or providing a positive recommendation for a promotion (Hudson et al., 2013).

Vic is a designer with a fashion magazine. He loves leading a relaxed, creative group of young designers as they prepare the next edition of the magazine. Part of his value to the firm is his ability to develop a creative team of designers to reach optimal productivity.

Roughly one third of American workers report that they experience some form of hostility from their supervisor at work in the form of being belittled, yelled at, or undermined. Typically, people in positions of authority are supposed to encourage and support those who work for them. However, when people in positions of power perceive threats to their competence or feel incompetent in a domain in which they are supposed to have authority, a likely reaction is to become aggressive. When bosses feel inadequate, they may lash out at those who are less powerful (Fast & Chen, 2009). It may not be possible for a new worker to achieve a good working relationship with a boss who is extremely defensive. Having an abusive supervisor is likely to produce negative emotions in the worker, resulting in work and job withdrawal. Especially among men, strong negative emotions produced by supervisory abuse are associated with an increased likelihood of quitting the job altogether (Atwater et al., 2016).

Demands and Hazards. Each job has unique occupational demands, including norms for self-preservation, productivity, and availability. In some work settings, the worker comes into contact with clients, patients, or customers who are very stressed, anxious, rude, or aggressive. The worker has to manage the hostile outbursts or attacks in a professional way in order to avoid escalation, but exposure to this type of negative affect can be very distressing for the worker who is trying to carry out a job as effectively as possible. For example, in some schools, teachers and other staff are exposed to student violence, creating a perception of a dangerous work environment. Experiences of victimization were linked to poor work engagement and high rates of staff burnout, especially in schools where staff perceived the school leadership as unable to limit or manage student violence (Bass et al., 2016).

A licensed vocational nurse described the tensions that come with being berated by a patient's family members.

> If you are working in an office and someone comes in and they're having words with you and maybe they're rude and you can say, "Listen, you've gone too far and you need to leave," whereas we have family members who come up to us and say, "How come you . . . ? How dare you . . . ?" And they can just be rude and say terrible things and we cannot, we really cannot, we really are not expected to, nor are we really allowed to answer back. (Bullock & Morales Waugh, 2004, p. 775)

Occupational hazards include a range of potential physical and psychological risks associated with the workplace, including exposure to toxins, work-related injuries, exposure to diseases or reproductive hazards, and working conditions that have negative psychological consequences, such as noise or shift work. The rate of work-related deaths and disabling injuries has decreased substantially since the 1960s. Nonetheless, in 2014, there were 4,821 deaths and 3 million disabling injuries and illnesses among U.S. workers in private industries, and over 700,000 injuries and illnesses among U.S. workers in public sector industries (e.g. police, firefighters, etc.) (U.S. Bureau of Labor Statistics, 2015b, c, 2016f).

Settings differ in the kinds of pressures or hazards they impose on workers. For example, mining is one of the most dangerous occupations. In 2014, 46 workers died in mining accidents, highlighting the fact that many workers continue to face hazardous conditions such as exposure to intense heat and humidity, exposure to toxic minerals and gases, poor air quality, and long hours underground (U.S. Department of Labor, 2016a). The most common source of fatal occupational injuries is transportation incidents, including crashes on public roadways (Byler et al., 2016).

Just as occupations vary in their risks, individuals differ in their vulnerability to occupational pressures and hazards, their willingness to risk certain potential dangers, and their evaluation of the payoff for enduring some degree of stress. People must ultimately decide whether the particular vulnerabilities are tolerable in light of the rewards.

In 2015, 17.5 percent of adults with disabilities were employed. Workers with disabilities were more likely than others to work part time, to be self-employed, and to work in service occupations. Since persons with disabilities were also likely to have fewer years of formal education, they were also less likely to be in management and professional occupations (Bureau of Labor Statistics, 2016g).

Interpersonal Relationships with Coworkers. The work setting can be a context for the formation of interpersonal relationships including friendship, collaborative teamwork, friendly competition, romantic feelings, and mentoring, as well as negative relationships like bullying, unwanted sexual attention or harassment, and hostile tactics that undermine the achievements of others. Although the potential for friendships in the work setting is usually not advertised as a central component of a job description, workplace friendships are often described as a key feature in the decision to be committed to a particular work setting. The need for friends with whom one can share the anxieties of learning the new job provides a strong motive for seeking comradeship on the job. The presence of congenial coworkers who can relax together and share feelings of accomplishment greatly enhances any work setting. In fact, the spirit of friendship on the job may compensate for many stressful situational demands. A workplace that creates space for collaboration and social interaction is likely to promote friendship formation and foster a more positive interpersonal environment.

Some work settings stress competition among coworkers; incentives are arranged to stimulate competition rather than cooperation. In such settings, new workers often must shoulder the strains of their new learning independently. Some settings create both competitive and cooperative norms by creating teams or production units that compete with one another for incentives. Under these arrangements intergroup relations tend to be more distrustful, whereas individual relations among team members tend to be more trusting and cooperative. The greater the commitment to the team's goal, especially under conditions of supportive leadership and encouragement for interdependence, the greater the team's effectiveness and the participants' sense of the team effort as a high-quality experience (Aubé & Rousseau, 2005). Knowledge sharing is one of the essential ingredients for successful team performance. However, in some settings, individuals who are rewarded for their individual achievement may be reluctant to share their knowledge or expertise with others, especially if this would result in reduced compensation for their individual performance. Support for shared leadership and shared knowledge within project teams may require the introduction of new limited-access web-based tools and new team-based incentives (Barnett & Weidenfeller, 2016; Jafari Navimipour & Charband, 2016). Many companies are introducing retreats that foster team-building and collaboration in order to bring a new spirit of interpersonal trust to the workplace.

Workplace bullying has become a growing concern. Managers recognize that bullying results in increased illness and absences as well as decreases in productivity (Meyers, 2006). Workers who have been bullied may be afraid or embarrassed to say anything about it. However, when interviewed about their experiences they describe the impact in powerful terms. "I feel that I have been maimed. . . . I've been beaten, abused, broken, scared. . . . I feel like I have 'kick me' tattooed on my forehead" (Tracy, Lutgen-Sandvik, & Alberts, 2006). The presence of egotistical, narcissistic, and aggressive coworkers can quickly disrupt the interpersonal climate of the workplace, making it harder to solve problems or collaborate on new initiatives. People who are exposed to insults or bullying at work are likely to suffer feelings of exclusion and depression, which may result in lashing out against other coworkers, thereby adding to the hostile climate.

Sexual harassment, defined as "unwelcome sexual advances, requests for sexual favors, and other verbal or physical harassment of a sexual nature... is illegal when it is so frequent or severe that it creates a hostile or offensive work environment or when it results in an adverse employment decision (such as the victim being fired or demoted)" (U.S. Equal Employment Opportunity Commission (EEOC), 2016). In 2015, the EEOC received over 6,800 allegations of workplace sexual harassment.

Many incidents of sexual harassment do not come to the level of federal investigation. A recent *Cosmopolitan* online survey found that in the more informal workplace, where coworkers interact on social media, through text messaging, and at informal gatherings, sexual harassment is pervasive.

> Roughly 1 in 3 women ages 18 to 34 has been sexually harassed at work, reveals our study of 2,235 fulltime and part-time female employees, conducted by the polling firm SurveyMonkey. The problem is at its worst in the restaurant industry, where 42 percent of women say they've experienced it, but it has also affected 36 percent of women in retail, 31 percent in science/tech, 31 percent in arts/entertainment, and 30 percent in the legal field. . . .
>
> *Cosmopolitan's* survey reveals a no-filter, say-anything workplace: Eight in 10 of those who were sexually harassed at work say it involves something said out loud. Forty-four percent of women who were sexually harassed say they've encountered unwanted touching and sexual advances. And about 1 in 4 have received lewd texts or e-mails. (Ruiz, 2015)

It is not uncommon for victims of sexual harassment to leave their workplace, thus suffering both humiliating abuse and job loss.

Poverty and Career Opportunities

Among the most obvious limiting factors the range of occupational opportunities open to a person during the work search phase are educational attainment, ability, and location. Discrimination on the basis of race and gender also continues to thwart the full participation of women and minorities in the workforce.

Since the 1970s there has been a growing gap between the quality of "good jobs" and "bad jobs" (Kalleberg, 2011). Factors including deregulation, global competition, increasing service sector work and declining manufacturing, weakening labor unions, and the reduced purchasing power of the minimum wage have all contributed to the expansion of precarious employment. Those with the most education are likely to be able to find jobs that have higher wages, some degree of job security, opportunities for control over their work schedule, and possibilities for advancement. However, a growing number of jobs pay low wages, offer few benefits, and offer no security. As a result, a large group of people are considered the "working poor;" they are working full time but are at less than 200 percent of the poverty level (Davis, 2010).

Recent economic conditions have added to a societal context in which relatively few resources are allocated to support low-income families. In a comparison of 21 rich nations, the overall poverty rate for all persons ranged from a low of 5.4 percent in Finland to a high of 20.2 percent in Mexico. The United States was second highest on the list, after Mexico. This dubious honor can be explained by a combination of two factors: (1) The United States has the highest proportion of workers in poorly paid jobs, and (2) the United States spends much less than most other countries on benefits that provide cash supplements, health, education, child care, or housing for low-wage workers (Smeeding, 2008). In 2014, about one third of the U.S. population earns 200 percent of the poverty level or less. The following example illustrates how close the working poor are to complete financial ruin.

> Karen Wall, 38, works as a teacher, cheerleading coach and weekend bartender. Yet money is tight, and all of it goes to keeping her family afloat and paying off her student loan debt. Both of her boys have special needs, so even with the multiple income sources, Wall knows she's only one disaster away from losing it all. "If I got in a car accident, I'd be homeless," she said. "If I get laid off from any of my jobs, my kids will end up going hungry." (Wing, 2014)

Successful programs that try to prepare individuals and families for self-sufficiency typically emphasize some combination of basic education, job skills training, and adaptive work orientation with supports such as child care subsidies and medical benefits. Some programs put more time and resources into improving the conditions of the jobs and fostering employee skills. Programs that combine work with career counseling, earnings supplements, health insurance, and child care subsidies have the combined benefits of decreasing poverty rates in a community, increasing long-term employment, and fostering children's well-being and school performance (Duncan, Huston, & Weisner, 2007). Nonetheless, the lack of jobs that consider the needs of single parents, families with children with special needs, or individuals with disabilities result in a constant struggle for significant subgroups of the population to find work that provides a healthy quality of life.

Career Phases and Individual Development

In an attempt to synthesize career and individual development, Kathy Kram (1985; Ragins & Kram, 2007) proposed a developmental model of career issues (see Table 11.3). Careers are delineated in three phases—early career, middle career, and late career—which correspond roughly to the phases of career exploration, career establishment and advancement, and career maintenance and disengagement. In each phase, career development reflects *concerns about self*, including questions of competence and identity; *concerns about career*, including questions of occupational commitment, advancement, and the quality of relationships in the work setting; and *concerns about family*, especially family-role definition and possible conflicts between work and family life. Typical issues facing the person at each phase are suggested in Table 11.3.

Issues of greatest concern during the early career phase reflect the need to demonstrate competence and to establish a satisfying lifestyle. Career development is never a completely rational process. As organizational loyalty gives way to a free-agent orientation to career development, individuals have to take a more assertive, risk-taking approach to their career development. In the early career phase, a person needs to reflect on his or her aspirations. This involves reviewing the central identity commitments that give meaning to one's life, including personal, career, and family values and goals. With respect to career goals, one must consider a mid-length time frame, looking ahead 3 to 5 years to think about the kinds of continuing education, experiences, and network of contacts that will contribute to the achievement of these goals. In this process, one confronts uncertainties about the meaning of work, worries about financial self-sufficiency, and potential conflicts between work and other spheres of life, especially intimate relations and family responsibilities.

In a survey conducted by the American Psychological Association, people were asked about various sources of stress in their lives (American Psychological Association, 2010). Even though about two thirds of the sample reported feeling satisfied with their jobs, 41 percent said they typically feel tense or stressed out during the workday. The younger workers, those in the age range 18 to 30, were most likely to report some lost productivity due to stress at work. Fears of the unknown—of taking on new responsibilities, of discovering the limits to one's abilities, and of disappointing important people in one's life—must all be faced and reframed if one is to achieve the adaptive flexibility necessary in today's world of work.

FURTHER REFLECTION: *Hypothesize about how meaningful work can stimulate adult development and how exploitation, discrimination, or thankless work can undermine development.*

What are your essential goals in the world of work? What steps are you taking to achieve those goals?

Lifestyle

OBJECTIVE 5 Examine the role of lifestyle development as an expression of an individual's personal identity, with consideration for the pace of life, balancing competing role demands, building a supportive social network, and adopting practices to promote health, fitness, and nutrition.

Table 11.3 Characteristic Developmental Tasks at Successive Career Stages

	Early Career	Middle Career	Late Career
Concerns about self	Competence: Can I be effective in the managerial/professional role? Can I be effective in the role of spouse and/or parent?	Competence: How do I compare with my peers, with my subordinates, and with my own standards and expectations?	Competence: Can I be effective in a more consultative and less central role, still having influence as the time to leave the organization gets closer?
	Identity: Who am I as a manager/professional? What are my skills and aspirations?	Identity: Who am I now that I am no longer a novice? What does it mean to be a "senior" adult?	Identity: What will I leave behind of value that will symbolize my contributions during my career? Who am I apart from a manager/professional, and how will it feel to be without the role?
Concerns about career	Commitment: How involved and committed to the organization do I want to become? Do I want to seriously explore other options?	Commitment: Do I still want to invest as heavily in my career as I did in previous years? What can I commit myself to if the goal of advancement no longer exists?	Commitment: What can I commit myself to outside of my career that will provide meaning and a sense of involvement? How can I let go of my involvement in my work role after so many years?
	Advancement: Do I want to advance? Can I advance without compromising important values?	Advancement: Will I have the opportunity to advance? How can I feel productive if I am not going to advance further?	Advancement: Given that my next move is likely to be out of the organization, how do I feel about my final level of advancement? Am I satisfied with what I have achieved?
	Relationships: How can I establish effective relationships with peers and supervisors? As I advance, how can I prove my competence and worth to others?	Relationships: How can I work effectively with peers with whom I am in direct competition? How can I work effectively with subordinates who may surpass me?	Relationships: How can I maintain positive relationships with my boss, peers, and subordinates as I get ready to disengage from this setting? Can I continue to mentor and sponsor as my career comes to an end? What will happen to significant work relationships when I leave?
Concerns about family	Family role definition: How can I establish a satisfying personal life? What kind of lifestyle do I want to establish?	Family role definition: What is my role in the family now that my children are grown?	Family role definition: What will my role in the family be when I am no longer involved in a career? How will my significant relationships with spouse and/or children change?
	Work/family conflict: How can I effectively balance work and family commitments? How can I spend time with my family without jeopardizing my career advancement?	Work/family conflict: How can I make up for the time away from my family when I was launching my career as a novice?	Work/family conflict: Will family and leisure activities suffice, or will I want to begin a new career?

Lifestyle is a social psychological construct that integrates personality characteristics, goals, convictions, and inner conflicts with social opportunities and resources into an organized pattern of actions and choices (Lombardi, Melchior, Murphy, & Brinkerhoff, 1996; Slavick, 1995). Simply put, a lifestyle is the self in action (Richman, 2001). Central components of the lifestyle include the tempo or pace of activities, the balance between work and leisure, the focus of time and energy in specific arenas, and the establishment of social relationships at varying degrees of intimacy. One's lifestyle guides decisions about how to organize time and prioritize the use of resources. One can think of lifestyle as the first translation of the values and commitments of individual identity into action through the devotion of time and energy to certain tasks and relationships and the development of domains of competence.

In the United States, a strong cultural assumption is that individuals are active agents who make choices (Savani et al., 2010). These choices reflect one's preferences and values. In early adulthood, the desire to create a life that is satisfying and meaningful is expressed through choices and decisions one makes about work, leisure, living arrangements, relationships, health, and **fitness**. In general, the more one perceives that there is freedom of choice about these decisions, the greater one's sense of happiness and satisfaction with life (Inglehart, Foa, Peterson, & Welzel, 2008).

Even though a person may experience considerable social pressure to build an identity around an occupational focus, the concept of lifestyle reinforces the idea that a person's work or career is not the same as a meaningful life (Allan, Douglass, Duffy, & McCarty, 2016). Because career choices can have such an impact on other aspects of life, it is important to select a career that supports a life, not the other way around. The following discussion illustrates some ways in which the overlapping systems of early adulthood—intimate relationships, parenting, and career—interact to organize characteristics of the lifestyle.

Pace of Life

Some counselors use the metaphor of a three-dimensional space to describe the lifestyle (Amundson, 2001). *Length* is the length of life, or where one is along a developmental continuum. For example, in early adulthood one is likely to view life as stretching out for many years into the future, as compared to middle adulthood when one is likely to think that one's life is about half over. *Width* is the busyness of life, including multiple role demands and how much activity one tries to jam into each day. *Depth* is the sense of purpose and meaning in life and the experiences of satisfaction or fulfillment that come with it. This three-dimensional configuration changes over the course of life, both as a result of personal changes in goals or developmental needs and as a result of situational changes in demands or resources.

The **pace of life**, or the busyness of life, is shaped by work, family, personality, and environmental context. For most young adults, the work setting largely determines the structure of time, including when one goes to work and returns, what one feels energetic enough to do after work, how much time is free for leisure or vacations, and the amount of preparation required during nonworking hours to prepare for the next day. People who are trying to combine parenting with a long workday experience the greatest time bind. Schedule control, rather than reducing the number of hours of work, seems to be especially important for helping people maintain a sense of lifestyle balance (Tausig & Fenwick, 2001).

Activity level, or the pace of life, is influenced in part by one's temperament, health, and fitness. This is a circular issue. Adults whose lives are very sedentary are likely to have lower levels of endurance and to feel the strain of daily exertion. Those who are more active and who include physical activity in their lifestyle are likely to have more energy and to be able to handle the demands of an active life.

The pace of life is also influenced by the climate and community. In a comparison of pace of life in 31 countries, the pace was faster in colder climates, more economically productive countries, and more individualistic countries (Levine & Norenzayan, 1999). In that study, Japan had the fastest pace of life. Pace of life may also be seasonal. In northern climates, for example, there may be fewer social events away from home during the winter, and life may therefore revolve primarily around the home. In spring and summer, neighborhood activities become a more important stimulus for social life as people emerge and renew their friendships. Rural communities often provide a calmer pace of life than urban communities. People often choose to live in rural or rural-like communities, even when they work in the city, to escape from the hectic pace of urban life. Pace of life is both a feature of personal lifestyle and a feature of a community or culture.

Social Network

Most people expand their social network during early adulthood. They form friendships in their neighborhood and at work. In some work settings, coworkers help each other balance their work and family life by taking shifts for one another, covering special family holidays, or carpooling to save expenses. Young adults may become involved in the social life of their religious community or civic associations. They may engage in community volunteer projects with friends and become more invested in the social needs of their neighborhood. If they have young children, the parents of other young children at the child care center or preschool may become important sources of social support. When options are possible, individuals often look for housing in neighborhoods where there are others in their same life stage and lifestyle orientation. For example, when couples with young children live in a community with other young families, they tend to rate the community more favorably than couples living in the community who do not have children (Swisher, Sweet, & Moen, 2004). The contribution of friendships to personal satisfaction and lifestyle differs widely during this time, with single adults and couples without children typically having more time for adult friendships than do parents.

The rapid and continuously expanding growth in the use of online social networking sites including Facebook, Twitter, and LinkedIn reflects the important role of social networks in the lives of contemporary young adults. There are over 2 billion users worldwide of online social networking sites, with the estimate projected to reach 3 billion by the year 2020 (Statista, 2016). About 90 percent of those ages 18 to 29 use these sites (Perrin, 2015). Social networking sites have a variety of functions, including staying connected with the activities of friends and relatives, sharing information and opinions about products or experiences, gaining recognition for accomplishments, and encouraging participation in upcoming events (Back et al., 2010; Boyd and Ellison, 2007). The online social networking sites function as

Tyler Olson/Shutterstock.com

The social network for new mothers often includes other new mothers who are facing similar demands and challenges. They discuss their strategies, share information and resources, and give each other emotional support.

mass communication vehicles powered by individual users who share their experiences and ideas with friends and associates. As these sites have grown, the possibility of making personalized contact with a wide and diverse audience has changed the nature and meaning of social networks so that they are now potentially quite vast, fluid, and include individuals who have never met face-to-face.

Online social network sites have become an indispensable resource for enacting and enhancing one's lifestyle. No matter what one's interests, hobbies, or needs, it is possible to find others who are willing to share their opinions or who have information about the availability, cost, and quality of community resources.

Striving for Work/Life Balance

A challenge faced in early adulthood is the management of competing role demands. Adults struggle with the tensions between the demands of the work setting and the demands of building an intimate relationship; with the tension between the desire to have children and the desire to achieve in the workplace; and with legitimate expectations for commitment to the worker role and the desire to experience fulfillment in other domains such as sports, arts, or community service. As more and more women with young children entered the labor market, the concept of work/life balance originally focused on issues related to conflicts between worker and parent roles. Research addressed the strains created by competing demands of work and family roles, including health-related impact, absenteeism, and reduced productivity (van Emmerik, Bakker, Westman, & Peeters, 2016).

Recent literature has expanded the idea of balance to consider the broader scope of work and *personal life,* reflecting the diversity of roles, commitments, and personal goals that dominate a person's lifestyle. The emphasis of this work is on approaches that support a healthy, satisfying quality of life for workers and a productive work/life organizational culture. Studies differ in how the term "balance" is defined and the factors that are considered important determinants for achieving balance. An ecological framework suggests that factors that contribute to the achievement of balance can be found at the individual, couple, family, job, corporate, and larger societal levels (Grawitch & Ballard, 2016).

For both men and women, the world of work is likely to provide the most rigorous test of commitment and the greatest pressures for productivity during the early adult years. For example, researchers have documented the impact of daily workplace events and the way men and women behave when they come home at the end of the day. At the end of a negatively arousing and stressful day of work, women are more likely to be angry at home whereas men are more likely to be withdrawn (Schulz, Cowan, Pape, Cowan, & Brennan, 2004).

Pressures in the work setting may come from a number of sources such as unpleasant interpersonal interactions, being bullied, increased pace and demands of work, feelings of incompetence, or frustration at being undervalued. Women who work full time in an inflexible work setting and who experience a high degree of work-related pressure have to deal with spillover into home and family life. This spillover competes directly with needs for intimacy and also with the time and energy needed for parenting. As a result, these women also exhibit a variety of depressive symptoms that make it difficult to cope with work demands. The greater these workplace stressors, the more likely they are to disrupt the quality of partner interactions at home, thereby reducing the availability of social support that might help buffer women from unrealistic work expectations (Goodman & Crouter, 2009).

As the opening case suggests, poor work/life balance can erode the quality of one's most valued relationships. It is also associated with a number of negative health consequences: fatigue, poor health, increased leg and back pain, stress-related impact on the immune system, loss of joy in living, and related depression and burnout (Mayo Clinic, 2015c).

In an analysis of the role demands of dual-earner families, researchers identified three distinct dual-earner lifestyles—high status, low stress, and main-secondary—each with its own pattern of role relationships, costs, and benefits (Crouter & Manke, 1997; Crouter, 2006). In the *high-status* couples, both partners had high-prestige careers, earned comparatively high salaries, and were involved in their work. In these couples, the division of household work was more equal than in the other two types. They experienced the greatest amount of role overload, had lower levels of love and marital satisfaction, and had more marital conflict than the other two groups.

The *low-stress* couples worked about the same amount of hours as the high-status couples, but their jobs were less prestigious. Examples were a mechanic and a secretary, and a salesman and a substitute teacher. Although the couples had levels of involvement similar to the high-status group, they had the lowest amount of role overload. This group had the highest scores in marital satisfaction and love for their spouse, and the lowest scores in marital conflict. These couples monitored their children more closely and seemed to be more accurate in describing their children's daily activities.

The *main-secondary* couples reflected a lifestyle in which husbands were the primary workers, with higher occupational prestige, more hours worked, and more work involvement than their wives, who typically worked part time. Women in these relationships had less education and tended to have more household responsibilities. A gender-typed division of labor was reflected in the pattern for female children, who performed more household tasks than girls in the other family types, whereas male children in these families performed fewer household tasks than boys in the other family types. This research illustrates the role of individuals and couples in managing work/life balance in part by decisions they make about the kinds of careers they pursue and the ways they support their partners' career choices.

Successful work/life balance depends upon a combination of personal coping strategies and workplace policies that support flexibility (Daverth, Hyde, & Cassell, 2016; Russo, Shteigman, & Carmeli, 2016). Given the vast differences in job demands and schedules, no one set of policies can apply across all workplace settings. The U.S. Department of Labor has created a Workplace Flexibility Toolkit to help workers, employers, and policy makers in identifying strategies that can address this importance aspect of modern life (U.S. Department of Labor, 2016b).

Health, Fitness, and Nutrition

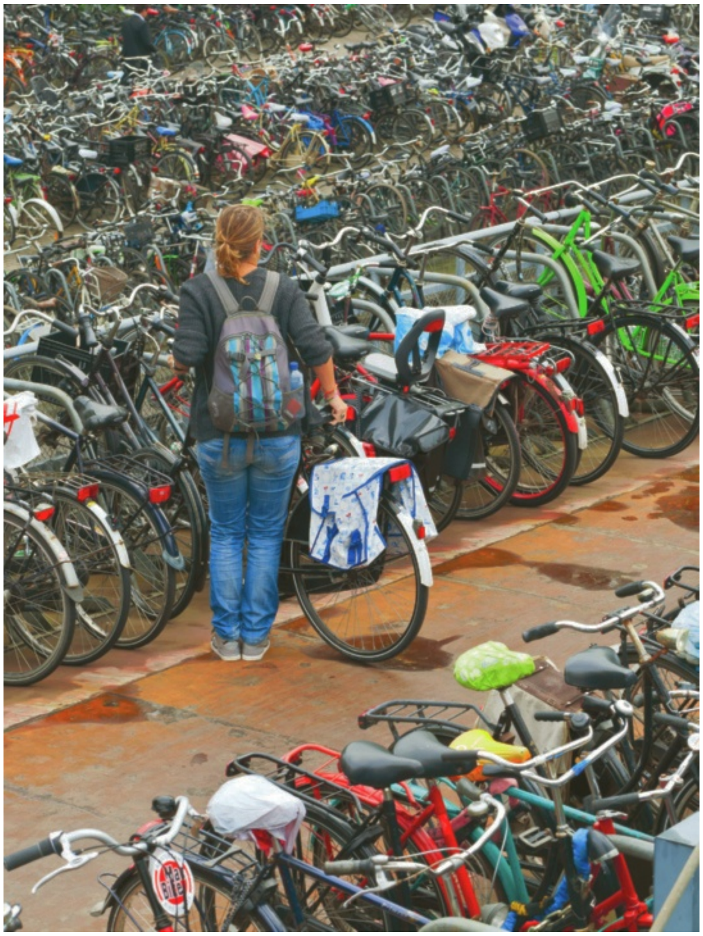
The contemporary emphasis on health, fitness, and nutrition highlights the importance of lifestyle decisions for illness prevention, wellness, and longevity. Research on health and health-related risks has begun to identify characteristics of a healthy lifestyle, including factors that operate at an individual level and those that reflect community commitment (see Healthy People, 2000, 2010, 2020). Leading health indicators include such practices as the use of preventive health services, regular exercise, eating a well-balanced diet high in fruits and vegetables and low in fat, avoiding smoking, limiting the number of sexual partners, and using contraceptives.

Many nutritionists recommend having a healthy breakfast, increasing the amount of fruits and vegetables, focusing on lean proteins, drinking 6 to 8 glasses of water a day, and eating 4 to 6 small meals rather than three big meals a day. Consider how often one of the following situations might interfere with a young adult's intention to eat a healthy, nutritious diet (Taylor, 2016):

- You have an unexpected early conference call, so you miss breakfast.
- You're at work and have an unexpected meeting to attend right before your usual break. No time to grab a snack.
- You're traveling; no chance to prepare healthy meals to take along.
- You're in a meeting and it's gone into overtime; you only have time to grab whatever is nearby (donuts or bagels).
- You're running errands and lose track of time, and there's nowhere to get a good healthy meal.
- You get home late; you're too stressed, too tired, or too overworked to eat a good nutritious meal and end up eating junk food.

An aspect of lifestyle that is often overlooked is the daily pattern of sleep and waking hours. A growing concern focuses on the large number of people who do not get the nightly sleep they require. This can lead to serious health problems, deficits in performance and alertness, increased risk of motor vehicle accidents, and impaired memory and cognitive functioning. In addition to problems with disrupted sleep or inadequate sleep, shifting one's bedtime by more than 2 hours can cause difficulties in falling asleep, staying asleep, or waking up on time and feeling restored by sleep (Vital Signs, 2010). Conditions of one's lifestyle, including living arrangements, the time one has to be at work or return from work; the noise level of the neighborhood; one's involvement in leisure activities including television viewing, online social networking, or gaming; and the use of drugs or alcohol, can all influence the amount and quality of one's sleep.

The concept of encouraging young adults to adopt a lifestyle that promotes health is becoming a focus for preventive health care. Lifestyle patterns established in early and middle adulthood, including one's diet, activity level, exercise, encounters with challenging and intellectually stimulating tasks, and reduced involvement with cigarette smoking and alcohol, all influence health and vitality in later life.



Shawn Hempel/Alamy Stock Photo

Here in Amsterdam, thousands of health conscious adults ride their bicycles to work, school, and recreational activities. You can see from the parking arrangements the vast number of people who use their bicycles daily.

Although the establishment of a healthy lifestyle can be viewed as an individual's responsibility, healthy communities are shaped by adults who share a common vision about the lifestyle they want for themselves and their families. Many aspects of fitness can be achieved at the individual or family level; however, some, such as air and water quality, access to health care, reduction of violence, or access to safe settings that promote physical activity, require a community commitment. Adults may join together to create resources and programs that increase the involvement of children and adults in regular physical activity. They may form a coalition of parents, health care professionals, educators, business leaders, and law enforcement agencies to devise a plan to decrease incidents of violence in their community.

Commitment to a healthy lifestyle may be enacted through efforts to improve air and water quality, reduce exposure to secondhand smoke, improve availability and access to health care services and health education, or increase support for environmental resources that sustain physical activity. For example, a report on walking and biking provides information about patterns of biking and walking in the 50 states, infrastructure that supports safe biking and walking, the relationship of biking and walking to health and well-being, and funding for projects that improve opportunities and resources for walking and biking (Steele, 2010). FIGURES 11.6 and 11.7 ▸ provide international comparisons for

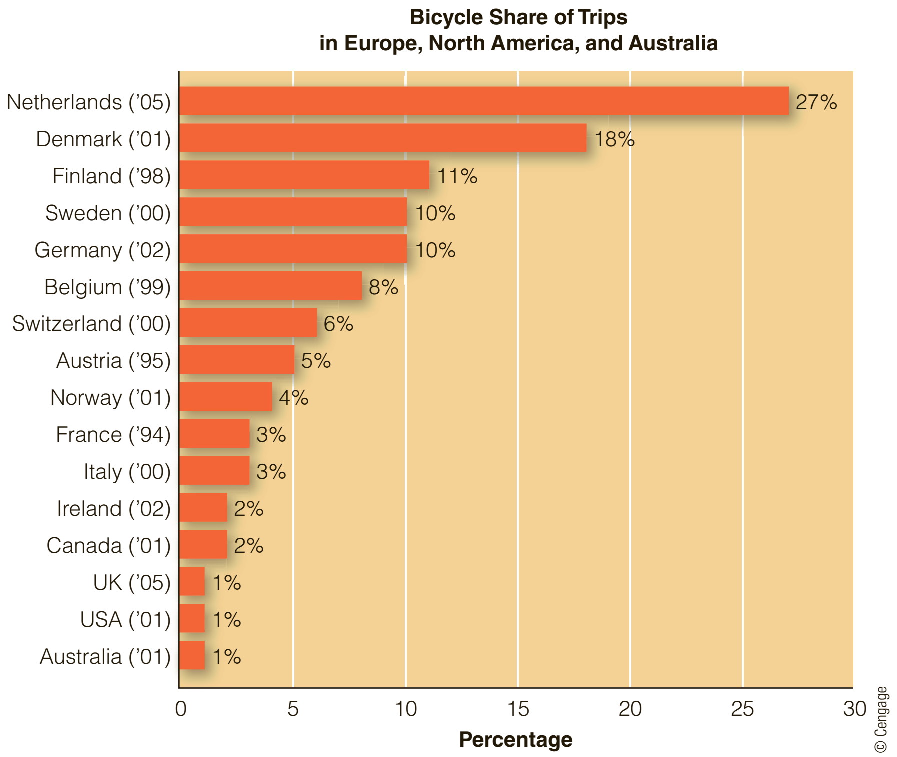


FIGURE 11.6 ▶ COMPARISON OF THE PERCENTAGE OF TRIPS MADE BY BICYCLE IN 16 COUNTRIES

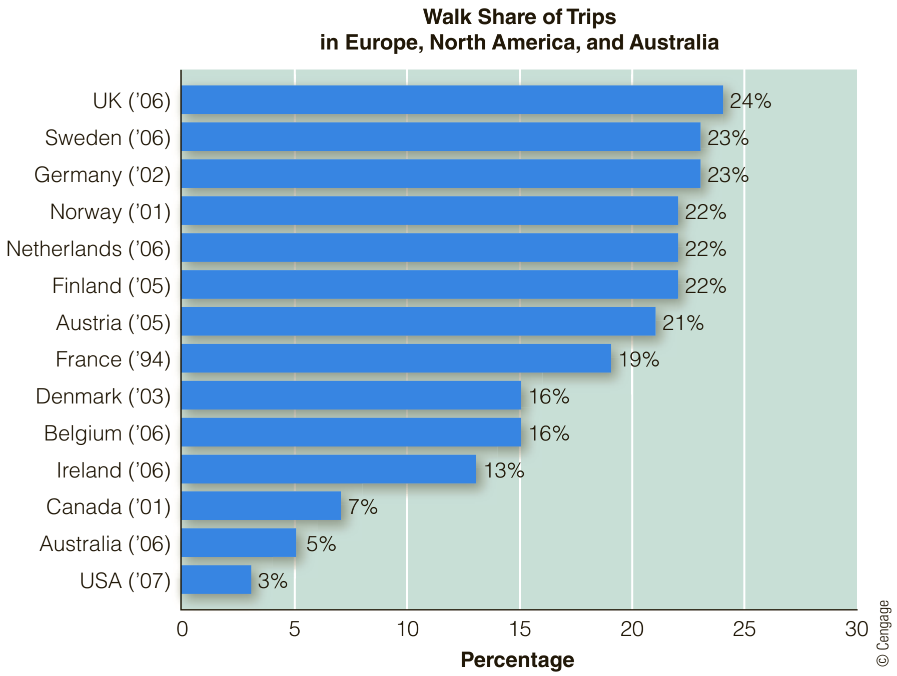

FIGURE 11.7 ▶ COMPARISON OF THE PERCENTAGE OF TRIPS MADE BY WALKING IN 14 COUNTRIES

the percentage of individual trips that are carried out by biking and walking in Europe, North America, and Australia. As the data show, people in the United States are at the bottom with respect to the frequency with which they bike or walk to their destinations. The relationship of limited physical activity to significant health problems, especially obesity, diabetes, and high blood pressure, is well documented. Efforts by communities to improve the infrastructure to support walking and bicycling can have important benefits for public health, as well as improvements in pedestrian safety and reduced traffic and air pollution.

FURTHER REFLECTION: Describe your current lifestyle. How do you use your time? What do you consider to be the essential structure of your lifestyle?

Are you comfortable and satisfied with the pace of your life and the meaningfulness of your lifestyle? If not, what could you do to modify your lifestyle?

The Psychosocial Crisis: Intimacy Versus Isolation

OBJECTIVE 6 Define and describe the psychosocial crisis of intimacy versus isolation, the central process through which the crisis is resolved, mutuality among peers, the prime adaptive ego quality of love, and the core pathology of exclusivity.

We have seen the importance of a sense of belonging in every stage of the life span. Accompanying these feelings of belonging, a sense of mattering emerges that helps a person experience the psychological and physiological benefits of social support. In contrast to the relationships that create a sense of belonging and mattering, some people are unable to engage in the trusting, open, mutually responsive relationships. They may experience rejection, exclusion, or an inability to accept the affection of others, resulting in a sense of isolation.

Intimacy

Intimacy is defined as the ability to experience an open, supportive, tender relationship with another person without fear of losing one's own identity in the process. An **intimate relationship** has both cognitive and affective components. The partners are able to understand each other's point of view. They usually experience a sense of confidence and mutual regard that reflects their respect as well as their affection for each other. Intimacy in a relationship supports independent judgments by each partner. It also permits the disclosure of personal feelings, as well as the sharing and developing of ideas and plans.

There is a sense of mutual enrichment in intimate interactions. Each person perceives enhancement of well-being through affectionate or intellectually stimulating interactions with the other (Erikson, 1963, 1980). Coming as it does after the establishment of personal identity, the possibility of establishing intimacy depends on individuals' perceptions of themselves as valuable, competent, and meaningful people. In an intimate relationship, the partners are aware of one another's aspirations. Under the best of circumstances, the partners interact in such a way as to promote one another's self-fulfillment, reassuring their partner about the possibility of achieving their most important goals and encouraging their self-actualization (Rusbult, Finkel, & Kumashiro, 2009). As exemplified in the following case study, intimacy also supports health and well-being. Intimate partners look after one another, respond to signs of stress or illness with concern, and monitor and contribute to one another's recovery during times of illness or injury.

— CASE STUDY In Sickness and in Health —

"Is that your husband?" The ER nurse is pointing to you, the fever-spiked lump who is snoring softly and muttering beside me. We've been here for hours, and for hours I've returned my lips over and over to your scalding forehead, as if to cool it, or, perhaps, to comfort myself. In just a little while longer, we'll find out that what you have is a severe case of strep, and you will swallow the prescribed pills, and I will finally put my lips to your quietly sleeping forehead and feel a welcome coolness. But for now the nurse's face is creased with compassion and weariness—she is waiting—and it's not really the right time to tell her about your gentle strength: the way you rocked our baby in the sling for hours on end while you graded papers, rocked another baby three years later while you did your anatomy homework, babies peacefully asleep across your broad chest for what feels like my entire adult life. It's not the right time to explain what a funny contradiction you are, a hockey-playing massage therapist, or how just last week you lay your hands on a friend's father while he lay dying in hospice. She wouldn't understand how funny it is that you gave me bedtime coupons—promising to turn in early on the nights I redeem them—because you're a night owl and I miss you in bed, or how it feels when I come down in the morning to a toasty kitchen because you've already lit a fire in our wood stove. She doesn't know that I'm strangely euphoric, sitting here thinking about how lucky I am to have so much to lose — my rock, my mystery, the love of my life—that I'm sitting here thinking *in sickness and in health*. *I will*, I think. *I do*. But all I can say is yes. "Yes. That's my husband."

Source: C. Newman (2009) *Redbook*, Is this what romance looks like?

CASE ANALYSIS Using What You Know

1. What evidence does this case provide about the feelings of intimacy?
2. How might experiences of a partner's serious illness or injury foster a sense of intimacy?
3. Although the narrative is told by one partner, what can you detect that suggests mutual regard and the partners' interdependence?

It is not difficult to understand that a person would be on intimate terms with parents and siblings. The family is a central context for sharing confidences, expressing love, and revealing weaknesses and areas of dependence. In fact, there is growing evidence that the nature of one's parental attachment orientation influences the ability to form new intimate relationships (Khalifian & Barry, 2016). The unique task of young adulthood is to establish an intimate relationship with someone outside of one's family. Two people who eventually establish intimacy may begin as complete strangers who have very few, if any, common cultural bonds.

The obstacles to attainment of intimacy in a romantic relationship are many. Some arise from childhood experiences of shame, guilt, inferiority, or alienation, which undermine the achievement of personal identity. Others result from incompatibility between partners. The number of adjustments that intimacy requires may overwhelm some young adults. Obstacles to intimacy derive from environmental circumstances that may erode the person's feelings of self-worth or interfere with the establishment of mutuality. These obstacles may be embedded in the socialization process as children learn distinct gender roles that introduce antagonism between men and women and foster interpersonal styles that stand in the way of forming open, caring interpersonal relationships.

Intimacy in the Work Setting

Although we tend to think of intimacy as a quality of romantic bonds, it is increasingly common for young adults to form close, intimate relationships with coworkers. Building on the experiences of group identity in early adolescence, young adults who achieved a positive sense of belonging in a peer group strive to reproduce this sense of loyalty, connection, and collegiality in the workplace. Affiliation and close friendships are likely to develop among coworkers. Workers may express devotion to an older leader or teacher, or with peers who share long hours every day in offices, schools, hospitals, and field settings. Through conversations around projects, solving team problems, attending conferences, or informal interactions on the golf course, the bowling alley, or at the tavern after work, coworkers can achieve an affectionate, playful, and enriching relationship. This kind of intimacy is demonstrated in the following reflection about a coworker.

> Alan was very influential. I respected him as being pretty sharp and pretty astute. He had a lot of guts to tackle the problems that existed in the area and that was the union-management business. I was really identifying with him in terms of what and how you run something, how you manage something. You would sit down and talk about or debate how you do certain things, what should we do in this kind of situation. We would be right in line. I think it was the way I came at a problem; it might be similar to the way he would come at a problem. (Kram, 1985, p. 33)

It may not be surprising to learn that having a "best friend" at work is associated with job satisfaction, engagement in one's work, and productivity. According to research gathered through a Gallup poll, about 30 percent of employees say that they have a best friend at work, and those that do are more productive, produce higher quality work, have a greater feeling of well-being, and are less likely to be injured on the job (Rath & Harter, 2010). Here are some speculations about the reasons for this link between having a best friend at work and positive work-related outcomes.

> [best] friends are more likely to invite and share candid information, suggestions, and opinions and to accept them without feeling threatened. Friends tolerate disagreements better than do those who are not friends. The good feelings friends share make them more likely to cheer each other on. Friends are more committed to the goals of the group and work harder, regardless of the type of task. (Wagner & Harter, 2008)

Despite the positive associations between having a best friend at work and both personal and work-related outcomes, some authors advise navigating these relationships with care. Information shared between close friends outside of work may slip out at work, undermining a friend's reputation or credibility. Best friends may find themselves in competition for a raise or promotion, resulting in hard feelings. In some situations, one person may be asked to provide evaluation to a supervisor about a coworker who is also a best friend, thereby creating an ethical conflict. When it comes to job security, pay, or advancement, close friendships may end up taking a second place to economic considerations or career success.

Isolation

The negative pole of the psychosocial crisis of early adulthood is **isolation**, a fear or unwillingness to have close, confiding, meaningful relationships. As social beings, people have a deep need for a sense of connection and belonging. Social isolation and the accompanying feeling of being unable to experience intersubjectivity or shared meaning are major sources of psychological distress (Jordan, 1997).

As with the negative poles of other psychosocial crises, most people experience some periods of the negative dimension of isolation. The more fully developed the ego becomes, the more it is characterized by clear boundaries. One by-product of individuality and independence is a heightened sense of separateness from others. During a period of intense personal growth and discovery, a person may experience interpersonal isolation, feeling preoccupied by thoughts and emotions that cannot be easily shared with others (Rokach & Neto, 2001).

Seven themes discussed in the following sections illustrate experiences of isolation: social anxiety, loneliness, depression, fragile identity, sexual disorders, situational factors, and drifting apart.

Social Anxiety

Isolation may come about because a person is anxious about all types of social activities (Cacioppo et al., 2000). They believe that success in social relationships is important but expect social encounters to be difficult and to end poorly. People who have high levels of **social anxiety** have a fear of being watched, judged, and criticized. They are very self-conscious in social situations, fearing that they will be embarrassed or humiliated. In anticipation of these possible outcomes, they avoid social situations, thereby minimizing exposure to potential negative experiences (Richards, 2016). The following narrative offers a glimpse into the challenges of daily life that are associated with social anxiety:

> Many times I'd be too fearful to speak up and be assertive at jobs. So, I'd get afraid and look like a "deer in the headlights." I didn't make good decisions at jobs. I had a hard time staying employed. I quit jobs I couldn't tolerate and got fired from others.
>
> I was fortunate to have great friends growing up, so I didn't struggle as much with social isolation as other social anxiety sufferers do. But then they went away to

> college, and I went to a different college than they did. I'd spend the whole weekend playing videogames (literally 20 hours+) because I was too afraid to go out and meet people. I wouldn't go to the gym because I believed people there were just waiting for me to "screw up" so they could "attack" me verbally. I didn't go outside for a jog as frequently for the same reasons. And asking people in class for their phone numbers? Forget it—too scary. It rarely happened.
>
> Even simple things like ordering food at a restaurant were hard. I'd get nervous and stutter when the waiter looked at me and forget what I wanted to order. Then on top of that, I'd get ashamed of myself afterwards for being such a "fool." (Stelter, 2014)

Not surprising, those with high levels of social anxiety are also uncomfortable about communicating with an intimate partner about sexuality, which in turn results in lower levels of sexual satisfaction (Montesi et al., 2013). Social anxiety disorder is the third most common mental disorder after depression and alcohol dependence, affecting over 19 million adults (WebMD, 2013).

Loneliness

Feelings of **loneliness**, a sadness when one's connection with others is disrupted or inadequate, can be separated into three categories: transient, situational, and chronic (Meer, 1985). *Transient loneliness* lasts a short time and passes, as when you hear a song or an expression that reminds you of someone you love who is far away. *Situational loneliness* accompanies a sudden loss or a move to a new city. *Chronic loneliness* lasts a long time and cannot be linked to a specific stressor. Chronically lonely people may have an average number of social contacts, but they do not achieve the desired level of intimacy in these interactions. Alana Massey reflects on the peculiar meaning of experiencing and expressing loneliness for this generation of young adults:

> Expressing loneliness has the rare distinction of making a person appear both pitiful and callous. As members of a generation raised on the virtues of self-esteem and self-reliance, confessing that we are lonely is to admit we've failed to sufficiently absorb the personal motto we were assigned from birth: "I am enough." Adding insult to injury, admitting loneliness to an audience of one or more puts the listener on the defense. "You've got me! Aren't I enough?" they reply, having so thoroughly internalized the self-affirmation that they have expanded "I am enough" to mean "I am enough for everyone." The assumption is a category error. I would be terribly lonely if I had a romantic relationship but no friends, but that's never happened. I have, however, experienced prolonged bouts of singleness, and the crushing loneliness those long stretches pressed onto me. (Massey, 2016)

Experiences of loneliness are associated with a variety of social skills and personality characteristics. People who have higher levels of social skills, including friendliness, communication skills, appropriate nonverbal behavior, and appropriate responses to others, have more adequate social support systems and lower levels of loneliness (Rokach, Bacanli, & Ramberan, 2000). In contrast, those who are lonely are more angry and anxious, have greater fear of negative evaluation, and a more pessimistic outlook about the future of a relationship (Cacioppo et al., 2006). Chronically lonely people are more likely to have a depressed immune system making them more vulnerable to illness. Their inability to form satisfying interpersonal relationships makes them vulnerable to exploitation, which creates a cycle of mistrust and social withdrawal (Cacioppo, 2008). Although it may seem logical to suggest that the lonely person should try harder to meet new people or develop new social skills, it is possible that the sense of isolation interferes with more active coping strategies (Goossens, 2012).

Depression

Depression is a worldwide health problem (Moussavi et al., 2007). When combined with one or more other chronic diseases such as arthritis, asthma, or diabetes, it substantially worsens a person's health. As a result, people who have a chronic health problem and depression are less able to engage in the kinds of social activities and pleasurable interactions that are likely to result in the formation of intimate relationships. Isolation may be a cause as well as a consequence of depression.

For some women, clinical depression appears to be linked to an orientation toward intimacy in which the self is systematically inhibited and devalued (Jack & Dill, 1992). They have a rigid view of how they should act in an intimate relationship, which is characterized by four major themes:

1. They judge themselves by external standards, feeling that they never quite measure up to what other people expect of them.
2. They believe they should build a close relationship with a man by putting his needs ahead of their own, and that to do otherwise is selfish.
3. They try to maintain a relationship by avoiding conflict and repressing their own views if they think those views may lead to disagreement.
4. They perceive themselves as presenting a false front in which they appear happy and satisfied on the outside although they are angry or resentful inside.

Over time, women who endorse this outlook lose contact with their authentic self, and even if the relationship remains stable, they become increasingly depressed. Longitudinal studies find that depression in one of the partners and relationship distress occur together. Depression has a negative impact on relationship quality, and poor relationship quality increases depression (Papp, 2010).

For some, the roots of depression begin in adolescence. Young people who tend to internalize their feelings under conditions of stress are likely to experience feelings of loneliness, lack of self-worth, anxiety, and depression. People who develop internalizing disorders in adolescence are at greater risk of continuing to experience depression as adults (Pine, Cohen, Gurley, Brook, & Ma, 1998). One of the most common stressors that may set off a bout of depression in adolescence is the breakup of a romantic relationship (Monroe, Rohde, Seeley, & Lewinsohn, 1999). As adolescents move into early adulthood, they may be more inclined to isolation as a way of protecting themselves from the depression that they have learned to associate with risks of rejection in romantic relationships.

Fragile Identity

According to the psychosocial perspective, work on personal identity precedes the capacity for adult intimacy. Longitudinal research that followed a group of adolescents from ages 15 to 24 supported this developmental sequence, demonstrating a clear relationship between the ego strengths associated with personal identity in middle and later adolescence with the capacity for mature intimate relationships in early adulthood (Beyers & Seiffge-Krenke, 2010). For some people, the possibility of closeness with another person seriously threatens the sense of self. They imagine intimate relationships to be a blurring of the boundaries of their own identities and cannot let themselves engage in them. People who fear a loss of identity continually erect barriers between themselves and others in order to keep their sense of self intact. Their fragile sense of self results from accumulated experiences of childhood that have fostered the development of personal identities that are either rigid and brittle or totally confused. Such a tenuous sense of identity requires that individuals constantly remind themselves who they are. They may not allow their identities to stand on their own strength while they lose themselves, even momentarily, in others. They are so busy maintaining their identities or struggling to make sense out of confusion that they feel isolated and cannot attain intimacy.

Sexual Disorders

Isolation may be linked to sexual disorders. Two widely cited desire disorders are *hypoactive sexual desire*, a decrease or absence of interest in sexual activity, and *compulsive sexual behavior*, a compulsive need to relieve anxiety through sex (Coleman, 2003). A loss of sexual desire is usually accompanied by physical withdrawal from the partner and by feelings of guilt and dread about losing intimacy. At the same time, the unafflicted partner often feels angry and guilty about imposing sexual needs on an unresponsive and uninterested partner, as in the following example.

> At first it was fun: feverish kisses in his red Chevy, giggly nights of passion in the apartment. But then came marriage, two kids, and suddenly her husband's hands on her flesh felt like tentacles, and the sight of him approaching made her body stiffen with revulsion. Then the disagreements began, hurtful scenes ending with each of them lying wedged against opposite sides of the bed, praying for sleep. (From L. Rosellini, 1992, "Sexual Desire," *U.S. News & World Report, 113*(1), p. 62. Reprinted by permission.)

In the case of compulsive sexual behavior, as in the following anecdote, sex is disconnected from pleasure or intimacy. Satisfaction of sexual drives is often accompanied by shame and disgust.

> Gary's pattern was always the same: First, the unbearable anxiety, never feeling good enough to handle the latest stress at his architect's job. Then, the familiar response—a furtive scanning of newspaper ads, a drive to a strip show, two straight Scotches to catch a buzz, and finally a massage parlor.... Afterward, he'd sit naked on the edge of the bed, his thought roiling in disgust: "I must be sick ... I can't change." But a few days later, the anxiety would begin again and he'd pore over the ads. (From L. Rosellini, 1992, "Sexual Desire," *U.S. News & World Report, 113*(1), p. 64. Reprinted by permission.)

Some psychologists view compulsive sexual behavior as an anxiety-based disorder, like other compulsions. Others argue that it is an addiction, like alcoholism. All agree that those who suffer from this disorder are not able to integrate sexual behavior as a meaningful component of an intimate relationship and therefore experience feelings of isolation.

Situational Factors

Isolation can also result from situational factors. A young man goes off to war in Afghanistan and returns after being seriously wounded, resulting in the amputation of his left leg. As a result of

iStockphoto.com/WillSelarep

Job loss is a common correlate of social isolation. Sarah stops to sit down and cry after having been laid off in a corporate restructuring. Her job was everything to her. She can't think of facing her family or her friends with this news. The idea of starting all over again to look for work is simply overwhelming.

his injuries, he doubts whether he could be an attractive or effective partner, and he is reluctant to engage in social activities to pursue romantic interests. A young woman rejects marriage in order to attend medical school and finds little time for the formation of intimate relationships. By the time she completes her internship and residency, she has many fewer options for finding an intimate partner. Due to the economic recession, a young adult loses her job, thus losing contact with many coworkers, and has to move to a new town to find employment. She faces the loss of multiple relationships in her social network as well as the undermining experience of unemployment. Under these and other similar circumstances, isolation is the result.

Drifting Apart

Isolation can arise even within an ongoing relationship. Some couples drift apart due to diverging spheres of interest and activity. For example, the partners may participate in distinct roles and activities. Marriages characterized by such a division of life spheres are sometimes referred to as *his-and-her* marriages (Bernard, 1972). The wife stays home most of the day, interacting with the children and the other wives in the neighborhood. The husband is away from home all day, interacting with his coworkers. When the partners have leisure time, they pursue different interests; for instance, the woman likes to play cards and the man likes to hunt. Over the years, the partners have less and less in common. Isolation is reflected in their lack of mutual understanding and lack of support for each other's life goals and needs.

In other cases, the partners create a widening body of unexpressed or undisclosed thoughts and feelings. They may have started out as a couple who could tell one another everything and share all their thoughts; but over time more and more topics become "hot" or uncomfortable. Talk about work is too upsetting; they disagree about politics; they can't talk about family members; and money is a source of tension as well. Eventually, the partners retreat into their own private worlds. They may go out to dinner, but have nothing to talk about; sit at home reading separate books they never discuss with each other; and spend time with separate friends. The feelings of closeness that accompany shared disclosure are lost, and replaced with a sense of isolation.

FURTHER REFLECTION: *Imagine a culture in which commitment to family and intimate relationships was valued above commitment to work. What policies and practices would provide evidence of this priority? How might the salience of these values influence the experience of development in early adulthood?*

The Central Process: Mutuality Among Peers

The central process through which intimacy is acquired is **mutuality among peers**. Mutuality refers to empathic awareness of one another, understanding of self and other, and the ability and willingness to regulate one's needs in order to respond to the needs of one's partner (Skerrett, 1996). John Gottman (2011) describes an essential feature of mutuality as **emotional attunement**, a couple's capacity to fully listen and understand one another, respect one another's opinions, and show affection. Through attunement, the couple can manage conflicts and reduce the strong negative emotions that may threaten to burst through from time to time.

mangostock/Shutterstock.com

Santiago and Alysse look into each other's eyes. They have just decided to get married, and that decision fills them with joy and hope.

The two young adults must bring equal strengths and resources to the relationship. Their intimacy is built on their ability to meet each other's needs and accept each other's weaknesses. When one partner needs to be dependent, the other is strong and supportive; at other times, the roles may be reversed. Each partner understands that the other is capable of many kinds of relationships. Mutuality facilitates the couple's ability to meet each other's needs in different ways over time rather than producing a static, unitary relationship. In fact, mutuality should enhance both individual and couple development. In the process of supporting each other, both partners perform in ways that they might not have adopted had they been alone (Van Lange & Rusbult, 2012).

The concept of mutuality has been used in previous chapters to describe the development of a sense of basic trust during infancy. In that context, the distribution of resources, experience, and strength is quite uneven. Mutuality is possible only because the caregiver is committed to the infant's well-being. Through caregivers' consistent efforts, children eventually learn to regulate their needs to fit the family pattern. However, children at this stage are not expected to be sophisticated enough to assess and meet their caregivers' needs. In young adulthood, the partners are responsible for fulfilling each other's needs. In most cases, there is no benevolent, superordinate caregiver. Just as the infant learns to trust the caregiver's ability to meet personal needs, each adult partner learns to trust the other's ability to anticipate and satisfy the partner's needs. By expressing trust and commitment to one another, each partner strengthens the other's ability to believe in and invest in the relationship (Avery, 1989). The partners may also realize that they depend on each other to solve the problems they face as a couple.

Mutuality in relationships has been studied by asking participants to read brief descriptions of relationship styles and to say which style characterizes their relationship with their mother, father, best friend, and romantic partner (Neff & Harter, 2003). Three relationship styles were described: one that emphasized autonomy and one's personal needs; one that emphasized connection and the needs and feelings of the other person; and one that described an effort to balance autonomy and connection by reflecting on what would be an effective response to the other person as well as meeting one's own needs. This last style was considered evidence of mutuality. Mutuality in a romantic relationship was associated with the most ideal outcomes, including relationship satisfaction, relational self-worth, and lack of relational depression. Think back to the process of individuation in later adolescence discussed in chapter 10. One can imagine that young people whose families had difficulty balancing autonomy and closeness while they were adolescents might have difficulty themselves in achieving this balance in order to create optimal mutuality in their intimate relationships (Kerig, Swanson, & Ward, 2012).

Mutuality is strengthened as the two partners learn to rely on each other and as they discover that their combined efforts are more effective than their individual efforts would be. Mutuality, like attachment, is a characteristic of the dyadic relationship rather than of the individual members in it. It is formed as two individuals, each of whom has a well-defined identity, discover that they can have open, direct communication, hold each other in high regard, and respond effectively to each other.

The Prime Adaptive Ego Quality and the Core Pathology

Love

Take 5 minutes and write down all the song titles you can think of that focus on the theme of love. For thousands of years, the nature of love and the qualities of a loving relationship have been described in songs and stories. In the resolution of the crisis of intimacy versus isolation in early adulthood, the ego quality of love emerges as the capacity for devotion and deep affection. Robert Sternberg (1988) described interpersonal **love** as a set of feelings, thoughts, and motives that contribute to communication, sharing, and support. According to his theory, almost all types of love may be viewed as a combination of three dimensions: *intimacy*, the emotional investment in a relationship that promotes closeness and connection; *passion*, the expression of physical and psychological needs and desires in the relationship; and *commitment*, the cognitive decision to remain in the relationship. These dimensions form a triangle that helps characterize the different types of love (see FIGURE 11.8 ▶). Each of these dimensions changes over time. Passion is the most fleeting and, without commitment, is likely to result in a short-lived love. Intimacy and commitment can grow stronger over time. However, if passion and intimacy both decline, commitment may dwindle as well (Belsky, 1997). An important aspect of this theory is that it helps account for many types of loving relationships including those that do not follow the romantic ideal of U.S. culture. Commitment, which may originate from valued kinship obligations or economic practicalities, can sustain a relationship and foster an enduring love with or without intimacy or passion.

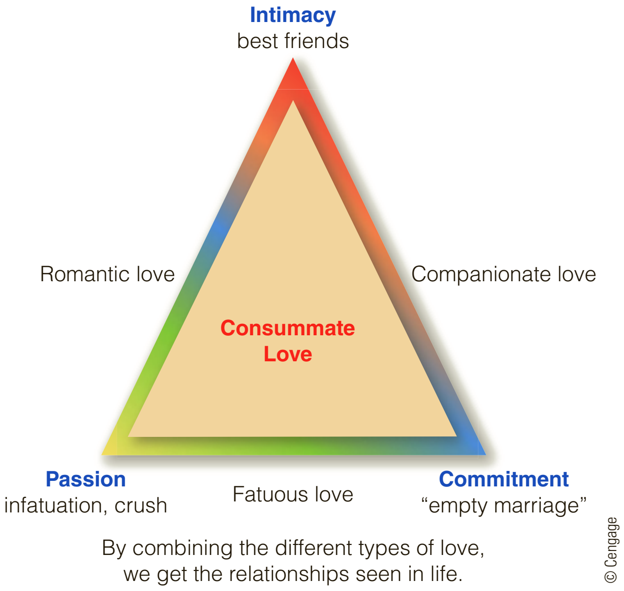

FIGURE 11.8 ▶ STERNBERG'S TRIANGLE OF TYPES OF LOVE

Conceptions of love usually include four aspects: ideas about the beloved, feelings that are associated with love, thoughts associated with love, and actions that are likely to occur between the lover and the beloved (Beall & Sternberg, 1995). The exact content of these feelings, beliefs, and actions differs from culture to culture, based on the culture's ideals about human nature, relationships, and cultural roles, especially courtship, marriage, childrearing, and religion.

In Western cultures, 10 components of a loving relationship have been identified:

1. Promoting the welfare of the loved one
2. Experiencing happiness with the loved one
3. Highly regarding the loved one
4. Being able to count on the loved one in time of need
5. Mutually understanding the loved one
6. Sharing oneself and one's possessions with the loved one
7. Receiving emotional support from the loved one
8. Giving emotional support to the loved one
9. Communicating intimately with the loved one
10. Valuing the loved one in one's own life

These 10 dimensions are present in relationships with parents, siblings, friends, and lovers. The weighting of the 10 components, however, may vary. Also, some love relationships include a dimension of sexual attraction, and others do not.

Romantic love has a motivational quality that is similar to other basic drives such as thirst and hunger. In brain imaging studies, people who have recently fallen deeply in love are shown photographs of their loved one (Aron et al., 2005). Although participants experience a variety of emotions, both positive and negative as they gaze at the photo, they all typically show activation of the area of the brain associated with motivation and reward, areas that are rich in dopamine production. In addition to other cognitive and affective characteristics of love, there is a neurological response associated with focused attention, new levels of energy, and feeling that a deep need is being satisfied. The association with dopamine-rich areas of the brain helps explain feelings similar to other types of craving, including mental preoccupation with the loved one, anxiety when separated from the loved one, and a desire to maintain contact with the loved one.

From an evolutionary perspective, it makes sense to think that features of love have adaptive value. The passionate and romantic features of love open a person up to including another person in one's life. In order to form a long-term relationship, a person has to reorganize activities, alter existing relationships, and modify living arrangements. All these changes require a lot of energy and time. The passionate and romantic feelings of love probably contribute to a person's willingness to make all these changes. In contrast, the dimensions of intimacy and commitment contribute to the ability to sustain a relationship over long periods of time. Love between partners must be sustained in order to have and rear children, accumulate resources, fend off competitors, and preserve the social bonds of the family and community. The feelings of companionate love help motivate a person to remain devoted to one's partner in order to maintain the family system (Reis & Aron, 2008).

Exclusivity

The core pathology of this period is **exclusivity**—a shutting out of others. To some extent, exclusivity is a natural element in intimate relations. For example, sexual exclusivity tends to be valued in monogamous sexual relationships. From an evolutionary perspective, women value their male partner's sexual exclusivity in order to ensure that his resources will be directed toward her and her offspring. Men value their female partner's sexual exclusivity in order to insure their paternity.

At some level, however, exclusivity can become destructive to one's ability to have relationships. Exclusivity of this type is characterized by intense jealousy, a rivalrous orientation toward anyone who shows an interest in one's loved one, and preoccupation with intense feelings of anger and resentment, both toward the loved one and toward others (Firestone, Firestone, & Catlett, 2006). The person has to expend tremendous energy monitoring the activities of the loved one. As a result, the person is cut off from relationships and ends up isolated. Ideally, the experiences of intimacy and love should broaden one's sense of connection and **social integration**. Through exclusivity, however, one's social support network is limited.

Exclusivity may be extended to the overestimation of one's family, religious group, and national group. Exclusivity may be expressed in various forms of prejudice including sexism, racism, and ethnocentrism. As the result of a belief about one's superiority, individuals become unwilling to seek out new people or new experiences. Exclusivity may limit one's willingness to entertain new ideas. In order to preserve the belief in the value of one's exclusive world, one has to distort reality, limit access to new information, and restrict movement in the social environment. Thus, exclusivity becomes a substantial impediment to coping.

Applied Topic: Divorce

OBJECTIVE 7 Investigate divorce as a life stressor in early adulthood, including the factors contributing to it and the process of coping with it.

Americans have one of the highest rates of marriage among modern industrial societies. Almost everyone in the United States wants to get married and does. However, the divorce rate is also high. In 2010, almost half of those in their late 50s who had ever been married had also been divorced or separated (Kennedy & Ruggles, 2014). In international comparisons, the divorce rate in the United States is higher than that of 34 other countries including the United Kingdom, Canada, New Zealand, and Australia (Cherlin, 2009). An analysis of the marriage history of a national sample of 3 million house units and 200,000 people living in group quarters provided an estimate of the duration of first marriages in the United States in 2009 (Elliot & Simmons, 2011). Thirteen percent of all first marriages had dissolved through separation or **divorce** at the end of 5 years; another 13 percent dissolved between 5 and 9 years; and an additional 22 percent dissolved between 10 and 19 years. Fifty-three percent of first marriages lasted 20 years or more. This study did not include information about the rate of dissolution of cohabiting couples, which would add another dimension to our understanding of relationship instability.

The focus of the following section is on the experiences of adults who are going through divorce rather than on the impact of divorce on children. Thus, our focus is on the nature of the divorce experience and its relationship to development during early adulthood.

Factors Contributing to Divorce

Following are some of the many hypotheses offered to account for the high divorce rate in the United States.

- We have an overly romantic idea about marriage; the reality of married life cannot live up to our expectations.
- We are overly individualistic and unprepared to make the commitment to achieve a collective goal.
- Men and women are socialized to fear and mistrust or devalue one another.
- We are an overly secular culture with too little commitment to religious values.
- The need for both partners to be involved in the world of work interferes with the establishment and nurturing of intimate relationships.
- Marriage is an outmoded institution, perpetuated by a patriarchal power structure.
- Women who work do not need to remain in unsupportive marriages.
- Men whose wives work do not feel obligated to remain in a marriage to support their wives.
- Smaller family size means less time devoted to childrearing, and more opportunity for nonparental, adult exploration.
- The longer life span makes it unrealistic that marriages can endure throughout adulthood.

- Children who experience insecure attachments and marital instability grow up to be young adults who are unable to sustain intimate relationships.
- Marriage is a status that requires access to financial resources; lack of equitable employment opportunities and high risks of unemployment threaten the stability of marriage among low-income populations.
- As the age at first marriage increases, people who get married are more “set in their ways” and find it difficult to adapt to the interdependence required of marriage.

A large number of variables have been examined as correlates or predictors of divorce. These analyses encompass cross-national studies, historical cohort analyses, multicounty comparisons, and cross-sectional comparisons of couples (Amato, 2010). At the societal level, countries where there are fewer women than men and where women marry at a later age have lower divorce rates. In traditional patrilineal societies, the social order is organized around families linked through ties of blood and marriage. Relationships are organized in a hierarchy of obligations and privileges that are maintained through an interdependence of family ties. Divorce rates are low in cultures where the stigma of disrupting a marriage is not only felt at the individual level but also results in harming important kinship bonds that are critical to the larger social structure (Savaya & Cohen, 2003). In countries or regions where traditional gender attitudes are combined with traditional division of labor, that is where men are in the labor market and women are responsible for the home, the divorce rate is lower. In countries or regions where women endorse more emancipatory gender values, divorce rates are higher regardless of women’s participation in the labor market (Gelissen, 2003; Kalmijn, De Graaf, & Poortman, 2004).

In a comparison of divorce rates across more than 3,000 counties in the United States, another important construct was identified—social integration, or the degree to which “people are tied or connected to one another, shared values being an important element in such integration” (Breault & Kposowa, 1987, p. 556). The characteristics of a community influence this sense of connectedness. Among the most significant of these characteristics are *population change*, the number of people who move in or out of a community each year; *religious integration*, the percentage of the population that belongs to a religious organization; and *urbanity*, the percentage of people in each county who live in an urban area. Divorce rates are significantly linked to each of these characteristics: They are higher in counties with high population change, low religious integration, and high urbanity. These findings suggest that the difficulties that individual couples experience in their marriages may be aggravated by the community context. In contrast, marriages may be buffered and supported by a sense of community identity and shared destiny (Rosenfeld, 2007).

In couple-to-couple comparisons, four variables have been associated with the likelihood of divorce: age at marriage, socioeconomic level, differences in socioemotional development of the partners, and the family’s history of divorce.

Age at Marriage

The relationship of divorce to age at marriage appears to be changing (see FIGURE 11.9 ▶). From 1970 to 2010, marriages among young people in the age groups 15 to 19 and 20 to 24 have been high. In earlier decades, the divorce rate showed a significant decline for those who married at the ages 25 to 29 and older. We can see the link here between the range of developmental differences between later adolescence and early adulthood including differences in the clarity of personal goals and commitments, maturation of executive functions, integration of one’s moral identity and opportunities to establish meaningful ties to community supports. However, in the recent period, 2008–2010, the decline in the divorce rate with age is much more gradual, with those marrying in their mid to late 30s showing a much higher rate of divorce than in any of the previous periods (Kennedy & Ruggles, 2014; Wolfinger, 2015).

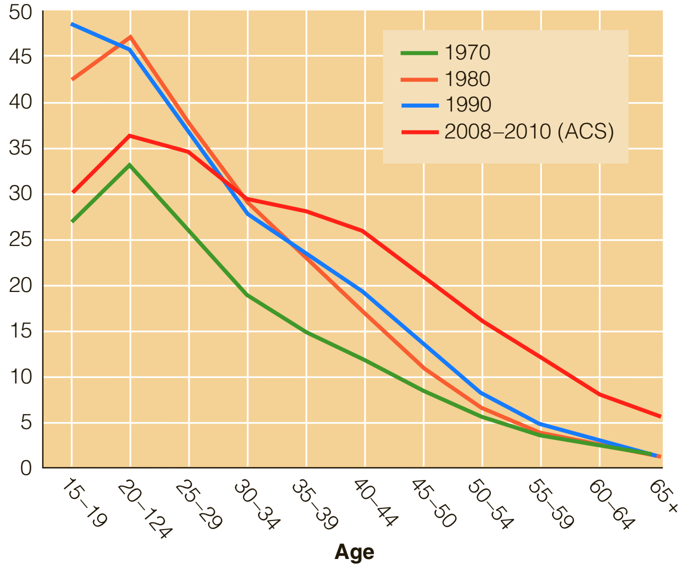

FIGURE 11.9 ▶ AGE-SPECIFIC DIVORCE RATES PER 1,000 MARRIED WOMEN, DIVORCE REGISTRATION AREA, 1970–2010

Source: Kennedy & Ruggles, 2014.

Both for couples who marry young and for those who marry later, dissatisfaction with role performance is a significant factor in marital instability. For young couples, dissatisfaction centers on sexual infidelity and jealousy. For older couples, it focuses on interpersonal conflict, a domineering style, and lack of companionship. Age at marriage is associated with different developmental needs and varying threats to marital stability. Of course, age at marriage is not a single explanatory dimension. For those who marry young, there is also a greater incidence of premarital pregnancy, dropping out of school, and lower-paying employment—all of which contribute to the likelihood of divorce.

Socioeconomic Level

The concept of **socioeconomic level** is a complex combination of education, occupation, and income. Each of these components is uniquely related to the divorce rate (White & Rogers, 2000). Men with more education have lower divorce rates. Women with more education also have lower divorce rates, except that those with 5 or more years of college are somewhat more likely to divorce than those who have had only 4 years (that is, have graduated from college). Within this overall pattern, there is also evidence of the **Glick effect**: Men and women who have dropped out of high school or college have higher divorce rates than those who have completed high school or college. Furthermore, those who have graduated from high school have a lower divorce rate than those who have had 1 to 3 years of college. Glick (1957) explained this pattern as evidence of lack of persistence. Those who are not able to complete a unit of schooling may also lack the resources to work at resolving the problems they encounter in marriage.

Many people believe that divorce is a privilege of the rich, but the evidence suggests that the opposite is true. The divorce and separation rates are generally higher among couples with minimal education and low incomes. Total family income is related to marital stability in some distinct ways. First, an erratic income and a high level of debt are more strongly associated with marital disruption than a low, steady income. Second, the relationship between income and marital instability is different for men and women. For men, higher income is associated with low divorce rates. For women, when wives contribute 50 percent to 60 percent of the total family income and when they express low to moderate marital happiness, divorce is more likely. When both partners bring about equal economic resources to the marriage, there is less of a sense of obligation to remain in an unhappy relationship (Rogers, 2004).

Socioemotional Development of the Partners

Socioemotional development is reflected in such dimensions as the partners' self-acceptance, autonomy, and expressiveness. Personality factors associated with emotionality and constraint have been linked with the risk of divorce. Both positive and negative emotionality increase the risk of divorce, whereas constraint decreases it. The genetic basis of these personality factors and the study of the link between personality factors and marital history among twins have led to the recognition that genetic factors play a role in the risk of divorce (Jersky et al., 2010).

Problems in communication are frequently cited by men and women as a major cause of divorce. Couples who are characterized as conflicted in their relationship during the premarital period, who have frequent disagreements, and who have different perceptions of how to resolve arguments are more likely to be separated or divorced 3 years after marriage (Fowers, Montel, & Olson, 1996). Generally, women experience more stress and report more problems in adjusting to marriage than men (Cotten, 1999). They tend to be more dissatisfied with the level of intimacy in their marriage than are men. These factors were examined earlier in the discussion of adjustment to marriage. Mutual satisfaction in marriage depends heavily on the husband's qualities. The stability of the husband's masculine identity, the happiness of his parents' marriage, his educational level, his social status, and his ability to be comfortable with the expression of emotions all affect marital happiness. Many husbands, however, enter marriage with a deep need to be nurtured and to continue the pattern of care that they received in childhood. The stability of a marriage depends on both partners' achieving a sense of their own identity. This achievement helps to establish the balance of power and mutual respect that is so central to emotional and intellectual intimacy.

Family History of Divorce

The partners' family history of divorce is yet another factor that contributes to marital instability. Children of divorced parents are more likely to get divorced than are children of intact marriages. A number of large national studies find that parental divorce markedly increases the chances that an adult child's marriage will end in divorce. For example, Amato (1996) reported that "the odds of divorce increased by 69% if the wife's parents had been divorced and by 189% if both the wife's and the husband's parents had been divorced" (Amato & DeBoer, 2001, p. 1038).

There are many interpretations of this *intergenerational transmission of divorce* (Amato & DeBoer, 2001). One interpretation is that, having seen their parents voluntarily end their marriage, children of divorce do not view marriage as a lifelong commitment and hold more favorable attitudes toward divorce as a reasonable strategy for resolving marital conflict (Greenberg & Nay, 1982). Another explanation is that children from single-parent and remarried families are likely to marry at an earlier age than children in intact marriages, thus increasing the probability of divorce. A third explanation is that parental hostility resulting in divorce harms children's psychosocial development. Children who have been exposed to high levels of negative affect and parental conflict may suffer from social anxiety, poor self-concept, and difficulties in concentrating, all of which may harm their ability to form supportive, intimate relationships in adulthood (Amato & Kane, 2011).

In a 17-year longitudinal study of marital stability, Amato and DeBoer (2001) were able to link the quality of the parents' marriage to the probability that their children's marriage would end in divorce. Of 335 married children, 20 percent had experienced a divorce or separation. Discord in the parents' marriage was not a strong predictor of divorce among the children. Rather, the study

Michael Newman/PhotoEdit

For couples who are dissolving a distressed marriage, hostility and resentment that have been characteristic of their relationship are likely to escalate during the divorce process. Despite the fact that attorneys are present, negotiations are likely to be riddled with angry interactions and communication failures.

found that children who divorced were in families in which there was relatively little conflict, but which nonetheless ended in divorce. This lends support to the explanation that these children are not as committed to a lifelong view of marriage. When marital unhappiness occurs, these children have less inhibition about ending the relationship, especially if a more attractive alternative is likely.

Coping with Divorce

Divorce is not a single event, but a relatively long process starting with thoughts about the possibility of divorce, through possible steps of marital counseling, reconciliation, mediation, trial separation, and legal action. It is an understatement to say that divorce is stressful. Divorce is associated with numerous losses, including the loss of financial resources, emotional support, one's marital and parental role, social support, and social integration (Fine, Ganong, & Demo, 2010). Loss of income may result in other kinds of material loss. For example, a divorced woman and her children may have to move to less expensive housing, sell many of their possessions, and leave the community where they have established a network of friends and social support.

Divorce can also bring role loss and social isolation. Even when a divorce is viewed as a desirable solution, the period from the suggestion of divorce to its conclusion involves a variety of decisions and conflicts that may be painful. In an analysis of a large national sample, researchers found that people experience increases in depression after divorce, regardless of whether they are leaving a negative marriage with high levels of conflict or a marriage that was not as unpleasant (Kalmijn & Monden, 2006). Divorced partners may lose contact with family and friends as each person's social support system takes sides in the split (Kunz & Kunz, 1995). In communities where there is high disapproval of divorce, men and women who decide to continue to live in their neighborhood following divorce are likely to suffer social rejection and loss of contact with neighbors and former friends (Kalmijn & Uunk, 2007).

Many people who experience divorce go through a time of intense self-analysis. They try to integrate the failure of their marriage with their personal definition of masculinity or femininity, competence as loving people, and long-held aspirations to enact the role of husband or wife, father or mother. The stress-related correlates of divorce include increased health problems, a higher incidence of suicide, and the overrepresentation of divorced adults in all forms of psychiatric settings (Stack, 1990).

The process of leaving a marriage is different for the partner who initiates the divorce than for the partner who is being left. The initiators view the process as more voluntary and tend to be more aware of support services and feel more in control, even if they experience some sentiments of self-doubt and redefinition. Those who do not initiate the divorce are more likely to experience a period of shock and disbelief. They, too, must go through a process of identity redefinition, which often takes longer and may be associated with stronger feelings of emotional turmoil (Duran-Aydintug, 1995; Vannoy, 1995).

Attachment to a Former Spouse

One challenge in coping with divorce is that many divorced people retain a strong attachment to their former spouse. Grief in divorce has been compared to bereavement in widowhood. In both cases, there is a loss and a need to adjust to it. Although the loss due to death may be more intense, especially if it is sudden, the loss due to divorce may be more bitter. If an intimate bond was once formed, there is certain to be ambivalence about losing it even when the divorce is desired.

In a study of more than 200 divorced people, 42 percent expressed moderate or strong attachment to their former spouse. Some people wondered what their former spouse was doing, spent a lot of time thinking about them, expressed disbelief that the divorce had really taken place, and felt that they would never get over it. The attachment was stronger for those who had not initiated the divorce. The lingering feelings of attachment were associated with greater difficulties in adjustment to divorce, especially problems of loneliness and doubt about being able to cope with single life (Kitson, 1982). The stronger the positive or negative post-divorce attachment, the more difficult the adjustment in the years following the divorce (Tschann, Johnston, & Wallerstein, 1989).

In contrast to mental preoccupation or rumination about a former spouse, many former spouses continue to have contact with each other. Divorced couples with children may be encouraged to maintain cooperative parenting arrangements that require ongoing conversations about the best interests of their child. These interactions are likely to preserve certain aspects of the relationship between partners that were formed during the marriage. In a Dutch study of about 1,800 former spouses, almost half continued to have contact 10 years after the divorce (Fischer, DeGraaf, & Kalmihn, 2005). Over time, contact with a former spouse decreases, especially antagonistic contact. Yet, even 10 years after divorce about 5 percent of the sample reported antagonistic contact, women reporting threats of physical harm from their former husbands and men reporting verbal aggression from their former wives. Contact was most frequent for couples who had children together before the divorce. For couples who did not have children, about 60 percent no longer had any contact with a former spouse 10 years after divorce. For couples with children, about 70 percent have contact with each other 10 years after divorce. For these couples, antagonistic contact declined and friendly contact increased over this time.

The fact that divorce is stressful and that people have lingering attachments to their former spouse does not mean that they consider the divorce undesirable. Studies that ask divorcing people what went wrong in the relationship suggest that for many, the conditions of the marriage were demeaning, exploitive, or oppressive.

> Common complaints by wives include their husband's authoritarianism, mental cruelty, verbal and physical abuse, excessive drinking, lack of love, neglect of children, emotional and personality problems, and extramarital sex.… More men than women describe themselves as having problems with alcohol, drugs, or physical abuse that contributed to the divorce.
> (Demo, Fine, & Ganong, 2000, pp. 283–284)

Many divorced parents report that, despite the difficulties of single parenting, life is more manageable than it was in the midst of the arguments and hostility that preceded the divorce.

Coping Strategies

Most people who experience divorce are determined to cope with the stresses it brings. Unfortunately, many adults do not anticipate the specific kinds of stressors that they will encounter. Of course, they have different coping strategies, some of which may not be effective for the special demands of divorce. In a longitudinal study that focused on how people adjusted to divorce, the researchers emphasized (1) the *kinds of stressors* that the individuals encountered, (2) the *resources* they had to help them cope, and (3) the *meaning* they gave to the divorce situation (Wang & Amato, 2000). The major stressors were large losses in income, losing friends, and having to move. Those whose post-divorce adjustment was most positive had higher income levels, were dating someone steadily or remarried, were most favorable about the marital dissolution before the divorce, or actually initiated the divorce. The magnitude of the stressors was not as important in predicting adjustment as were the coping strategies (resources and meaning).

In another study comparing widowed and divorced women, the contribution of social support to coping was examined in more detail. Those women who were most stressed by their loss received increased social support from friends and relatives in the following year. For the two groups, the most beneficial type of support differed. For widows, practical support, such as transportation or help with household chores, was positive; for those who had been divorced, having someone who would listen to their personal problems was especially helpful. For both groups, receiving monetary support was associated with an increase in distress. Thus, some types of social support appear to foster recovery, whereas others may serve to highlight the extent of one's loss (Miller, Smerglia, Gaudet, & Kitson, 1998).

It is not uncommon to read narratives that describe the personal and interpersonal growth that accompanies effective coping with divorce. Erin Smith (2015) described important ways she matured after 4 years in a troubled marriage.

1. After spending time in therapy, she learned that by understanding more fully who she was she could also be better at forming relationships.
2. She realized that after 4 years of being told that she was a terrible person, she had been beaten down. After the divorce, she learned to be more accepting of herself.
3. She realized that she had given up many of the things that had made her happy. After the divorce she rediscovered those activities.
4. She learned that in a "normal relationship" she should expect someone to treat her with kindness and respect.

Divorce is typically accompanied by a diversity of emotions including grief, anger, guilt, depression, fear, and self-doubt. It may also involve feelings of identity confusion, numbness, and loss. Coping typically requires some time to allow the grieving process to unfold, facing these emotions and finding ways to manage them. In addition to psychotherapy and support groups, coping strategies might include the following: striving to regain a healthy lifestyle including diet, exercise, sleep, and other positive routines; using a journal to provide an outlet for feelings and thoughts; making a list of enjoyable distractions that can be used when feelings of numbness or depression seem overwhelming; exploring some new interests or returning to earlier hobbies that bring feelings of competence and self-worth (Dombeck, 2016).

Coping with divorce requires strategies devised to deal with the aspects of it that are perceived as most troublesome. Further, many coping strategies, including becoming involved in new activities, spending more time with family and friends, gaining new skills, or taking a new job, may promote new levels of functioning. Human service professionals can be effective in helping adults develop coping skills for resolving some of the stressors of divorce and transforming a difficult life event into an opportunity for personal growth.

FURTHER REFLECTION: *Account for the high divorce rate in the United States. Distinguish five or more levels of explanation: historical, economic, cultural, familial, and personal. How are the developmental tasks of early adulthood related to the challenges of divorce? How might the circumstances of the divorce determine the most effective coping strategies?*

CHAPTER SUMMARY

OBJECTIVE 1 Define and explain selected theoretical concepts that are especially relevant for understanding development during adulthood, including social roles, the life course, and fulfillment theories.

Three theoretical concepts were introduced to help consider the challenges and directions of growth in adulthood: social roles, the life course, and fulfillment theories. Adulthood comprises a series of increasingly complex and demanding roles, experiences of role gain and role loss, and new challenges of balancing multiple roles. The life course perspective is a framework for examining adulthood as the interface of family and occupational careers against the backdrop of chronological age, historical period, and societal norms and expectations. Through the life course lens, one gains appreciation for the developing person and the changing historical context. Fulfillment theories emphasize the ability of adults to go beyond meeting daily needs and achieving equilibrium to make plans, strive toward goals, and seek personal meaning in life.

The developmental tasks of early adulthood require that individuals apply the many competencies they have acquired in childhood and adolescence to solving new and complex challenges. They may marry or make a commitment to an intimate partner, have children or decide to delay or forgo childbearing, and choose work roles. Gradually, they evolve a style of life. In this process, their commitment to social institutions and to significant others expands. Their worldview becomes more diverse, and their appreciation of the interdependence of systems increases. One of the major sources of stress at this life stage is the need to balance and integrate multiple roles.

OBJECTIVE 2 Analyze the process of forming intimate relationships, including initial attractions, mate selection, and commitment to a long-term relationship. Contrast the ways that different patterns of cohabitation contribute to the formation of close relationships. Summarize the challenges one faces in adjusting to the early years of marriage.

The exploration of intimate relationships requires a readiness to engage in the complex set of dyadic interactions that move a relationship from initial attraction to deeper levels of disclosure, role compatibility, mutual support, and commitment. These close relationships can take a variety of forms, some of which set the stage for long-term commitment and others that seem to be more marginal or temporary. A major theme in the establishment and maintenance of satisfying intimate relationships is the quality of communication and the ability of couples to coordinate their interactions, particularly under conditions of conflict or role strain.

OBJECTIVE 3 Describe the factors associated with the decision to have children, and evaluate the impact of childbearing on intimate relationships.

The decision to have children is becoming increasingly one of choice rather than obligation. Age at childbearing is delayed in line with later age at marriage. At the same time, there is an increase in nonmarital childbearing and in voluntarily child-free couples. Having children alters the adults' intimate relationship, especially the amount of time parents spend with one another when the children are not present. Couples differ in the ways they balance their roles as parents and intimate partners; some couples grow closer and more companionate, whereas others experience new levels of conflict and declines in marital satisfaction.

OBJECTIVE 4 Define the concept of work in early adulthood and explore how work stimulates psychosocial development.

In the period of occupational training, many new areas of intellectual awareness are stimulated. Self-understanding is integrated with social expectations and historical opportunities as men and women embark on their career paths. The nature of the world of work and the possible kinds of jobs and careers are rapidly changing. A growing concern is the divide between "good jobs" and "bad jobs," leaving many young adults in jobs that have little security, few benefits, and low pay. Four components of the work environment must be mastered: technical skills, authority relations, interpersonal relations with coworkers, and ways of coping with the demands, hazards, and risks of the workplace. Career development implies changing phases of emphasis and preoccupation with self, family, and occupational goals. One of the most challenging aspects of career development in this early phase is the coordination of work with the establishment of meaningful intimate relationships.

OBJECTIVE 5 Examine the role of lifestyle development as an expression of an individual's personal identity, with consideration for the pace of life, balancing competing role demands, building a supportive social network, and adopting practices to promote health, fitness, and nutrition.

Lifestyle is the translation into action of the values, goals, and personal preferences that were crystallized into a personal identity in later adolescence. Components of lifestyle that impact the sense of well-being and personal life satisfaction include the pace of life, the quality of one's social network, the ability to balance competing role demands, and behaviors that contribute to one's fitness and overall health.

OBJECTIVE 6 Define and describe the psychosocial crisis of intimacy versus isolation, the central process through which the crisis is resolved, mutuality among peers, the prime adaptive ego quality of love, and the core pathology of exclusivity.

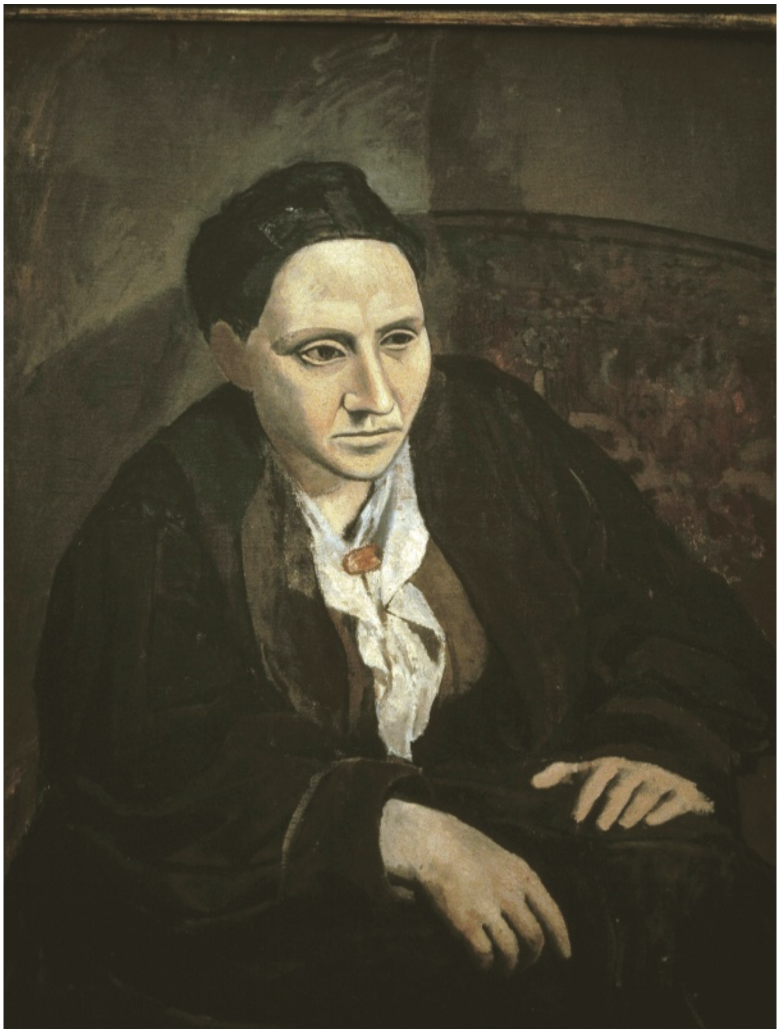
The psychosocial crisis of intimacy versus isolation emphasizes the evolution of adult sexuality into an interpersonal commitment. This crisis requires that needs for personal gratification be subordinated to needs for mutual satisfaction. Success is comparatively difficult to achieve in our culture because of the basic tension between the norm of independence and the desire for closeness. The varieties of circumstances and personal characteristics that can result in a sense of isolation are discussed. The research on marriage suggests that willingness to make a personal commitment to another adult is one of the key aspects of success. The elaboration of communication skills, the ability to engage in and resolve conflict, and the ability to find time for companionate, leisurely interaction are emphasized as central to marital stability.

OBJECTIVE 7 Investigate divorce as a life stressor in early adulthood, including the factors contributing to it and the process of coping with it.

The high rate of divorce suggests that many societal, community, and interpersonal factors work against the support of stable intimate relationships. Linked to the increase in the age at first marriage, there appears to be an increasing risk of divorce among those in their 30s. In the process of coping with divorce, there is a clear need for daily problem solving and emotional expression to manage the grief, loss, and role transitions that accompany the disruption of an intimate relationship.

CASEBOOK

For additional cases related to this chapter, see the case entitled "To Marry or Not," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 163–170. The case focuses on the development of Jonah's and Abby's dating relationship, their decision to marry, and the early years of their married life as they are influenced by work and extended family relationships.



Album/sfgp/Newscom

Gertrude Stein was Picasso's friend and mentor. She provided an environment where creative people could get together and share ideas. This portrait was the only one that Stein felt represented her true sense of self. Middle adulthood is the period when one's energy and talent are directed toward building and maintaining the structures upon which future generations depend. It is the stage when self-fulfillment is integrated with caring for others.

LEARNING OBJECTIVES

1. Analyze features of the world of work as a context for development, focusing on interpersonal demands, authority relations, and demands for the acquisition of new skills.
2. Define the concept of a vital, intimate relationship and examine factors that support this goal in middle adulthood, especially a commitment to growth, effective communication, creative use of conflict, and preserving passion.
3. Evaluate the expansion of caring in middle adulthood as it applies to two specific roles—that of a parent and that of an adult child caring for one's aging parents. Clarify your assumptions about the costs and benefits of enacting these roles.
4. Summarize the tasks required for effective management of the household and explain why they are necessary. Describe the diversity of households, including blended families, single-parent families, and adults who live alone, and hypothesize about the implications of these various household structures for individual development.
5. Define and explain the psychosocial crisis of generativity versus stagnation and the central processes through which the crisis is resolved: person–environment interaction and creativity, the primary adaptive ego strength of care, and the core pathology of rejectivity.
6. Apply a psychosocial analysis to the issue of discrimination in the workplace, and evaluate the cost to society and to the individual when discrimination operates to restrict career access and advancement.

Chapter Summary

— CASE STUDY Reinventing Family in Middle Adulthood —

This dad started his blog when he was in his late 30s in anticipation of the birth of his first child. Now he is divorced, in a new relationship, and marveling at the possibility of life in a blended family.

The Girlfriend and I have been living together for almost a year now. Since we both have joint custody of our children, this means that for 50% of our time, we have three children from two separate marriages living under one roof.

It's pure heaven and we don't take any of our happiness for granted. Luck and fate somehow conspired to bring us together. For that, we're eternally grateful.

When the Boss Lady and I split up, I was forty years old with a four-year-old daughter. I had no idea what was in store for my future and my mind raced with a million questions.

> Will I ever find someone who shares my perspective on life?
>
> Does that woman even exist?
>
> Will she mind that I have a kid?
>
> Will she even like kids?
>
> What if she wants one of her own?
>
> What if she already has kids?
>
> What if her kids hate me?
>
> What if my kid hates her?
>
> What if the kids hate each other?

The Girlfriend and I have been extremely lucky to find one another. I'll get into the trial and tribulations of forming a modern-day blended family in another post but, right now, I'll just say that things are going great.

The two of us have a very loving relationship, and it's important for us to show our kids what a healthy relationship looks like. We're firm believers that children live what they learn. But in a way, that's all besides the point. What makes all of it so much easier is the fact that our kids truly do love one another. They love like sisters. They fight like sisters. And they make up like sisters.

While the Peanut may have had a bit of a tougher time acclimating from being an only child to a middle one, it's been a major adjustment for all of us. Yet despite the fact that so many things could have gone wrong, we couldn't be happier about how well things have worked out. Three girls under one roof can be intimidating but, at the end of the day, they care for each other. They love one another. And they're lucky to have one another. What more could two divorced parents ask for?

Blog from "Microphone Check, One, Two…," by MetroDad, May 2013. Retrieved June 10, 2013.

CASE ANALYSIS Using What You Know

1. Evaluate the assumption that children live what they learn. What evidence supports the idea that the quality of parenting is a major influence on the development of children as they mature into adolescence and adulthood?
2. Describe the features of a healthy relationship in middle adulthood. What features of the partners and the couple contribute to a healthy relationship?
3. Given what you learned about divorce in chapter 11, what challenges do you expect this man to face in adjusting to divorce and to the new intimate relationship?
4. Reflecting on this case, describe the new outlook on parenting, intimacy, and meaning in life that may emerge in middle adulthood.

Middle adulthood lasts from about age 34 to 60. According to psychosocial theory, a new reorganization of personality occurs that focuses on the achievement of a sense of generativity—a concern about the well-being of future generations. This new stage integrates the skills and perspectives of the preceding life stages with a commitment of energy to the future. During this period, individual and societal development are intimately interwoven. In order for societies to thrive and grow, adults must dedicate their energy and resources to preserving the quality of life for future generations. In order for individuals to continue to thrive and grow, societies must provide opportunities for adults to express and fulfill their generative strivings.

The current cohort of middle adults is sometimes referred to as Generation X, born between the 1960s and 1980. They are a noticeably smaller generation than the older baby boomers or the younger millennials, coming of age in the 1980s and 90s, and associated with the popular culture of MTV, video rental stores, and cable television. Generation X experienced the end of the Cold War, with the fall of the Berlin Wall, and the splitting apart of the Soviet Union. Ronald Reagan, George H. W. Bush, and William Clinton were the presidents during their "coming of age" years. Among other events, these years brought heightened awareness of the AIDS virus and its impact on the gay community, the emerging use of the World Wide Web, the bombing of the Oklahoma City federal building, and the founding of Google (Robinson, 2016; Taylor & Gao, 2014). Generation Xers have been described as accepting of diversity, pragmatic, and self-reliant/individualistic. Many saw their parents getting laid off, and have redefined corporate loyalty; they take employment seriously but dislike rigid, authority relations; they prefer having autonomy to learn new skills and devise new approaches in order to get the job done. They are somewhat pessimistic about the future of their retirement (Thielfoldt & Scheef, 2004).

Because middle adulthood covers a relatively long period, there are opportunities to review and revise one's commitments and goals along the way. People experience many transitions in their work and family roles during this time, encountering a widening circle of relationships and new responsibilities for the care and guidance of others. Many situations call for decisions that have no single correct answer. Several alternatives are possible, and adults must rely on their ability to gather and evaluate information to determine which choice is best for them and their loved ones. Flexibility coupled with a good sense of humor and creative problem solving emerge in this stage as key coping strategies. ●

Developmental Tasks

Every adult typically engages in all of the following developmental tasks during middle adulthood: managing a career, nurturing intimate relationships, expanding caring relationships, and managing the household. Through their roles in the family, at work, and in the community, middle adults have broad responsibilities for the nurturance, education, and care of children, adolescents, young adults, and older adults. The strains of middle adulthood result largely from difficulties in balancing many roles and striving to navigate through predictable as well as sudden role transitions. The emotional well-being of the society as a whole rests largely on the capacity of middle adults to succeed in the developmental tasks of this life stage.

Managing a Career

OBJECTIVE 1 Analyze features of the world of work as a context for development, focusing on interpersonal demands, authority relations, and demands for the acquisition of new skills.

Work is a major context for adult development. Every person who enters the labor market has an occupational **career**. However, this career may not appear to be orderly or progressive. It may involve changes in the kind of work performed over time, short- or long-term exit from the labor market due to unemployment or family responsibilities, and periodic return to school for new training. One can argue that as long as a person is involved in an effort to make use of **skills** and talents, there will be significant interactions between the world of work and the person's individual development.

Using the framework of systems theory, one can appreciate that the microsystem of work is embedded in a larger societal macrosystem. Each society has an economic orientation that influences policies and practices related to work. The climate for the U.S. worker is one that encourages a relatively long work week and few benefits. For example, there is no law requiring companies to provide paid vacation. In comparison to European countries, the labor union structure is less powerful in the United States and often cannot protect workers from new demands for productivity. According to data gathered by the Organization for Economic Cooperation and Development, the average U.S. worker works over 1,790 hours a year. This is over 250 hours a year more than in Denmark, France, Germany, Netherlands, or Norway, but less than in Chile, Korea, Greece, Mexico, or Poland (OECD, 2016). Over the period from 2004 to 2013, an average of 5.2 million employed workers ages 25 to 54 were working more than one job (Lalé, 2015). The demands on U.S. workers are substantial, resulting in significant role strain as middle adults strive to balance work with other important life roles, especially those of parent, caregiver for aging parents, intimate partner, and community member.

The buying power of wages has declined, so that most families find it necessary for both partners to work in order to have a reasonable standard of living. The costs of housing, education, and health care have increased dramatically, and the projection of a longer life expectancy has placed new pressures on workers to save for a more diverse set of needs in retirement. The costs of medical care adds to the financial worries of many middle adults, both out of concern for their ability to pay for their own immediate family's medical expenses and for their ability to support their aging parents whose health care costs are often not fully covered by insurance. All these features of the macrosystem in the United States have implications for the way individuals orient to the world of work and for the potential conflicts between work and family life (Warren, 2003/2016, 2007).

There is reciprocity between work experiences and individual growth. People with certain kinds of experiences, abilities, and values will enter certain kinds of work roles (Holland, 1997). Once those roles have been entered, the work environment and the kinds of activities that the person performs also influence intellectual, social, and value orientation. One's lifelong occupational career is a fluid structure of changing activities, ambitions, and sources of satisfaction. As people move through middle adulthood, the management of their occupational career becomes central to their sense of personal effectiveness, identity, and social integration. Four themes in the management of a career are discussed for their contribution to adaptation and individual development: achieving new levels of competence, midlife career changes, balancing work and family life, and the impact of joblessness.

Achieving New Levels of Competence in the World of Work

Middle adulthood brings new challenges, a reformulation of ambitions and goals, and new levels of competence in the workplace. Three areas are emphasized here as they relate to the interpersonal and cognitive components of career development: understanding and managing leadership and authority

relationships, expanding interpersonal skills and relationships, and achieving new levels of mastery in critical skill areas.

Understanding and Managing Leadership and Authority.

Authority relations encompass all the hierarchical relationships that give people decision-making power and supervisory responsibility for others. Returning to Tiedeman's model that was introduced in chapter 10 (Later Adolescence), in the *induction* phase of career development one must identify the authority structure operating in the work setting and begin to establish one's position in it. In the *integration* phase, which typically occurs in middle adulthood, advancement in a career inevitably involves taking on positions of increased responsibility and power to make decisions. Career advancement means assuming authority in some areas, while recognizing the authority of others. However, not everyone in a position of authority provides effective leadership. A common complaint among workers is that their organization lacks leadership, or that their boss or supervisor does not provide adequate leadership.

What is **leadership**? Organizational theory suggests that leadership is not a quality of personality as much as it is a relationship among people. Woyach (1991) defined leadership as "the process of helping a group shape a vision of its purpose and goals and of getting people, both inside and outside the group, to commit and recommit themselves to accomplishing that vision" (p. 7).

This definition embodies three basic assumptions: (1) Leadership is a relationship among people, (2) leaders provide a sense of vision or direction, and (3) leaders motivate the group to work toward achieving its vision. Building on this view of leadership, Woyach (1993) argued that effective leaders try to balance the good of the group with their own self-interest. They try to take into account the best interests of individuals, groups, and communities while they also participate and lead.

The requirements of leadership may change as the group develops and as the team or organization faces new, emerging challenges. Groups may go through phases when everyone is overloaded and distracted. During those times, leaders help the group return to its mission and recommit to working together by communicating a clear, coherent sense of direction that others can understand and follow (Dewan & Myatt, 2008). At other times, the group members may understand their roles and tasks so clearly that the primary acts of leadership involve delegating responsibilities and removing obstacles to the group's success. Effective leadership involves the ability to assess the changing needs and challenges faced by the team or organization and to adapt to those changes through the use of flexible problem-solving strategies. **Adaptive leadership** is required when the organization faces new conditions or complex problems that cannot be solved with the current use of technologies or techniques. Under these conditions, leaders need to help frame new ways of defining problems and engaging workers, consumers, or clients in a search for solutions (Heifetz, Grashow, & Linsky, 2009).

Some requirements of leadership are perceived differently across cultures. For example, in a study comparing full-time, white-collar workers in China and Australia, participants were asked to rate traits that were important for effective leadership. The Australians, who expect their leaders to be able to work collaboratively with employees, rated friendly and respectful traits higher than did the Chinese workers. For the Chinese workers, a hierarchical authority structure is valued. A person in a leadership position might be perceived as weakening authority through friendly interactions with subordinates (Casimir & Waldman, 2007).

Other aspects of leadership appear to be universally effective. Leaders who are described as charismatic or visionary are more likely to be rated as highly effective by their subordinates. Charismatic leaders are able to convey a vision by distilling complex ideas into a simple message and linking their message through symbols, analogies, or stories to experiences that are personally relevant to their followers. Charismatic leaders are confident and optimistic. They might be idiosyncratic or theatrical in their approach and inspirational in their delivery. They are willing to take risks and often suggest a direction that is a noticeable departure from the way the organization has been heading. Charismatic leaders are sensitive to the needs of their members and actively monitor and listen to people at all levels of an organization in order to retain rapport with their group members and to stay attuned to changes in the organizational climate (Conger & Kanungo, 1998).

Across many types of groups and different degrees of organizational complexity, charismatic leaders encourage followers to become deeply committed to the organizational mission, make

Team members are pleased that he respects their ideas and provides this mechanism for them to express their ideas as they build the vision for the future.

personal sacrifices for this mission, and perform above expectations (Maxwell, 2011). They do this in part through their positive and encouraging emotional messages and their ability to form constructive relationships with workers. Under the guidance of this positive leadership, workers are happier, less likely to miss work, and more willing to engage in training and development activities (Campbell, Ward, Sonnenfeld, & Agle, 2008; Den Hartog, De Hoogh, & Keegan, 2007; Erez, Misangyi, Johnson, LePine, & Halverson, 2008; Rowold & Laukamp, 2009).

The reorganization of many large companies has resulted in fewer employees, who are then asked to be more productive. In this context, leaders need to develop adaptive leadership to accompany their technical expertise. This involves communicating a clear view of the challenges, mobilizing and guiding the direction of innovation, coordinating people and projects, and increasing workers' willingness and readiness for change. Adaptive leadership may involve increasing employees' sense of confidence in their ability to initiate changes as well as increasing their commitment to the organization during a period of uncertainty or transition (Heifetz, Grashow, & Linsky, 2009; Strauss, Griffin, & Rafferty, 2009).

The idea that leaders are able to motivate others is explored in detail by Rosabeth Moss Kanter in her analysis of how organizations are able to turn a losing streak around. Based on hundreds of interviews and a national survey of more than 1,000 companies, Kanter (2004) identified strategies that successful leaders use to encourage members of their organization to reach new, higher levels of performance. When leaders believe in the goals of the organization and in the ability of people to achieve those goals, people will rise to meet those expectations. In inspiring confidence, leaders set high standards and are role models for these standards. They establish systems for individual and system accountability. They foster collaboration through mutual respect and effective communication. They recognize and encourage initiative, imagination, and innovation. They are able to convince others outside the organization to invest in the goals of the organization, which makes their success more attainable. Thus, it falls to the leader of a group to embrace a vision of success and to build commitment to that vision rather than to be caught up in the many obstacles that prevent success.

The focus on leadership highlights the importance of ego strengths for middle adults in positions of authority, not only for their own personal occupational achievements but also for the future of organizations and the well-being of workers. Especially during periods of uncertainty and transition, middle adults who are optimistic, flexible, open to new ideas, and confident can create environments where people are able to address their work in a productive, proactive manner. Through effective leadership, middle adults convey a vision about the possibilities for their organization and guide others toward the achievement of this vision. Success in this enterprise contributes to the sense of meaning and mattering, essential elements of subjective well-being in adulthood.

Expanding Interpersonal Skills and Relationships.

Many occupations place a great deal of emphasis on the development and use of **interpersonal skills**—especially the ability to interact well with customers and coworkers and the ability to communicate effectively—as criteria in the selection and promotion process. Interpersonal skills include at least three components: self-presentation, or how a person introduces oneself to others and conveys openness to further interactions; social scanning, or the ability to read the social cues in the situation; and social flexibility, or the ability to respond adaptively to the social demands of the situation, for example by being assertive or cooperative as the circumstances require (Wu, 2010). Even if these skills are not mentioned explicitly in the job description, success in career management requires the ability to influence others, appear credible, develop a fluent conversational style, and learn to work effectively in groups or teams. Problems in interpersonal relationships can have a negative impact on employees, on the image of the organization, and on overall productivity.

Another essential feature of many work environments is the ability to work in teams or groups. Teams that work well together are able to maintain positive social relationships among the members as they work to complete their group's tasks, all the while supporting the personal and professional development of team members. Eight features of effective teams, many of which reflect the importance of interpersonal skills and relationships, have been identified in the literature (Marquardt, Seng, & Goodson, 2010):

1. Clear and meaningful goals
2. Clearly stated expectations for positive interpersonal behavior
3. Strong interpersonal and communication skills
4. Competence and commitment to solving problems and performing tasks
5. Trust, openness, and group cohesiveness
6. The ability to manage conflict to preserve positive relationships among members
7. Shared leadership
8. Continuous individual and team commitment to learning and improvement

When individuals work in teams, especially when there is frequent interaction, there is a tendency toward **social comparison**. One may learn that a colleague has made a lot of sales, received recognition for an accomplishment, or solved an important work-related problem. This might be viewed as an *upward* comparison—a person believes that the colleague performed better than others. In contrast, one may learn that a colleague made a lot of errors, worked too slowly, or failed to make a sales quota. This might be viewed as a *downward* comparison—a person believes that the colleague performed worse than others. Social comparison is an ongoing aspect of the interpersonal environment at work, with some people being more likely to base their self-evaluation on comparisons with others (Buunk et al., 2005).

In a cooperative work environment, people view the fate of their colleagues as directly affecting each member of the team. In such a setting, one can imagine an interpersonal dynamic such that people feel proud of those who are doing better than they are and are encouraged to seek out these high performers to learn from. People who feel bad when others are not doing as well as they are may be willing to help them raise their skills or improve their performance.

Those in leadership positions have an opportunity to foster a cooperative or competitive work climate and to manage the process of social comparison in the interest of productivity or effectiveness. More senior workers are often in a position to influence the interpersonal atmosphere, serving as models for others, demonstrating pride in their achievements, providing encouragement for appropriate work-related behavior, and fostering respect and trust among coworkers.

Whether a person is in a supervisory role or not, experienced and highly qualified workers can be extremely valuable to newer workers as **mentors**. Among the major Fortune 500 companies, over 70 percent have a mentoring program to help workers manage the demands of their job, make wise career decisions, and progress through the milestones of career advancement (Wharton School, 2007). The mentor–mentee relationship may be informal or assigned. In either case, the mentee is hoping to find someone who will provide safe, confidential advice; honest feedback; and insights into how to succeed. Mentors need to be sensitive to the needs of the mentee and their career ambitions, be able to convey the values and organization of the corporate culture, and help link the mentee to an expanded and varied network of colleagues. Effective mentors are "trustworthy, accessible, sincere, and active listeners. [They] have mentoring experiences, professional experience, a good reputation, and a large professional network" (Giancola, Heaney, Metzger, & Whitman, 2016, p. 212). Successful mentor–mentee relationships involve a good matching process including shared interests, commitment to the relationship, and a willingness on the part of the mentee to accept feedback and follow through on recommendations. Whereas having an effective mentor is clearly beneficial for the career and psychosocial well-being of the mentee, this kind of interaction has also been found to have benefits for the mentor. By interacting with their mentee, the mentors can learn new aspects of their organization, get insights into new technologies, and expand their network through the mentee's contacts. The success of the mentee becomes a source of pride for the mentor, and in some cases, the mentee's success can be of direct benefit to the career advancement of the mentor (Giancola et al., 2016; Wharton School, 2007).

Meeting New Skill Demands. The characteristics of the occupation and the work setting determine what kinds of work-related skills will dominate the adult's energies. It makes sense to expect that the actual tasks a person performs from day to day will influence their intellectual development. The *Dictionary of Occupational Titles* (U.S. Department of Labor, Employment and Training Administration, 1993) was updated and converted to a Web-based resource called *O*NET* by the U.S. Department of Labor, Employment and Training Administration. O*NET describes and updates over 900 occupational titles with regard to skills, abilities, knowledge, tasks, work activities, work context, experience levels required, job interests, and work values and needs. Each of these dimensions has implications for workers' adaptation to their work setting. In the process of adapting to these dimensions, adults often carry over aspects of work-related competence to family and community roles.

The idea that social structure influences personality through occupational demands was developed in some detail by Melvin Kohn (1980, 1999). One of the strongest relationships he identified was between the *substantive complexity* of the job and *intellectual flexibility*. **Substantive complexity** is the degree to which the work requires thought, independent judgment, and frequent decision making. Those whose work is characterized by substantive complexity also tend to have relatively low levels of supervision, and their work is not overly routinized. As a result of these work conditions, they tend to value self-direction, encourage self-direction in others—including their children—and show evidence of **intellectual flexibility**, the ability to handle conflicting information, grasp several perspectives on a problem, and reflect on one's own values and solutions.

This relationship between substantive complexity at work and personal intellectual flexibility was found among workers in the United States, Poland, and Japan (Kohn, 2006). In the cross-national comparison, U.S. workers whose jobs were characterized as substantively complex also had greater personal satisfaction and a sense of well-being, whereas those whose work was highly routinized and supervised had a lower sense of well-being. In contrast, in Poland, when these data were collected in 1978, the workers who had the more substantively complex work were also more distressed. The workers at the more routinized jobs were more confident of job security and less threatened by instability. Although the Polish workers at the routinized jobs had the least self-direction of all three countries, they felt a high sense of satisfaction about their current and future employment. However, the managers, whose jobs were more substantively complex, were also at greater risk. They were held accountable for productivity with little opportunity to influence rewards or working conditions.

One of the most frequently cited areas of skill development in the contemporary labor market is *creative problem solving.* The combination of increasingly complex technology, instant international communication, and continuing reorganization of the network of interrelated businesses results in the emergence of a new and changing array of problems. These problems may relate to the need to recruit and train the workforce, bring together changing teams of workers depending on the task, find new strategies for the manufacture and delivery of products, or integrate technologies. The concept of **managerial resourcefulness** captures the nature of this problem solving. Managerial resourcefulness combines three critical features: a cognitive capacity to gather and analyze information, sensitivity to the emotional and motivational aspects of change, and a readiness to take appropriate actions (Kanungo & Menon, 2005; Kanungo & Misra, 1992).

By middle adulthood, individuals have accumulated a deep knowledge of the specific tasks and routines associated with their work. At the same time, they have either tried or observed a variety of problem-solving strategies. Thus, the challenge for the middle adult worker is to synthesize these two bodies of knowledge to create a flexible approach to emerging problems. Successful development in this area requires recognizing when conditions have changed such that past solutions will not be adequate. At the same time, it requires confidence in one's ability to find new solutions and remain creative under stressful conditions.

Midlife Career Changes

Management of a career does not necessarily mean remaining within the same occupational structure throughout adult life.

Recall from the discussion of work in chapter 11 (Early Adulthood) that between the ages of 18 and 48, the average number of jobs held was 11.7. Although the rate of job turnover slows down after age 30, people still need to remain flexible about their attachment to a specific job. The segment of workers employed fulltime by corporations is a shrinking percentage of working-age adults. A growing number of middle adults are experiencing work-role transitions, including new assignments within the same company, the same type of work in a different company, combining self-employment with part-time work, and making a transition into an entirely new field of work (Mahler, 2011).

As today's working-age labor force moves through middle adulthood, from age 34 to 60, the nature of the labor market is also changing to a more decentralized, fee-for-services model. This requires individuals to create a "portfolio approach" to their career—developing a document that is more detailed and three-dimensional than a resume that highlights one's products, skills, talents, and experiences (Handy, 1996). The portfolio approach assumes that people need to market themselves, whether in hopes of advancement within a company, or as they seek new employment opportunities. People who change jobs relatively often or who work as consultants and project managers can take this approach in order to convey the range of skills they have developed and the diverse products or activities in which they have played a major role.

Work activities or work-related goals may change for at least six reasons during middle adulthood. First, some careers end during middle adulthood. One example is the career of the professional athlete, whose strength, speed of reaction time, and endurance decline to the point where the athlete can no longer compete.

Second, some adults cannot resolve conflicts between job demands and personal goals. Some workers recognize that the kinds of contributions they thought they could make in the workplace are simply not possible within their chosen work structure. Others feel like outsiders within their corporations.

> Trish Millines Dziko didn't discover her affinity for computers until she attended college on a basketball scholarship. Later, while she was rising through the mostly White, male ranks at Microsoft, she felt uncomfortable being one of the few African Americans in Redmond. At age 39, she retired as one of many Microsoft millionaires and used $100,000 of her kitty to establish the Technology Access Foundation, designed to bring more kids of color into the game. . . . "I want to change the dynamics of the [corporation] club," says Dziko, "by changing the demographics." (Schultz, 2001, pp. 68–69)

A third explanation for midlife career change is the realization that one has succeeded as much as possible in a given career. Adults may realize that they will not be promoted further or that changing technology has made their expertise obsolete. Consequently, they may decide to retrain for new kinds of work or return to school to move in new career directions.

Fourth, family transitions may prompt career changes. In some instances, adults leave the labor market or move to part-time work in order to care for their children or their aging parents. In other cases, adults enter the labor market following divorce or widowhood. According to a New York Times/CBS News/Kaiser Family Foundation poll of people who were not in the labor force, 61 percent of women and 37 percent of men ages 25 to 54 said that family responsibilities were the reason they were not working (Miller & Alderman, 2014).

Fifth, with the restructuring of the workforce, some workers are laid off and cannot be rehired in the same field. They have to retrain for a new line of work or for similar work in a new industry. Other workers may remain with the same company but find that they are being asked to perform new tasks that require a new set of skills and responsibilities. When people are laid off, they may have to find work that is below their level of training and previous salary.

Sixth, some jobs are too stressful or physically demanding to continue over many years. In order to preserve their physical and/or mental health, people may have to find a kind of work that is a better fit with their energy, physical strength, and coping capacity.

One must be cautious not to idealize midlife career change. It is not uncommon to experience a variety of fears or worries about leaving one occupation and starting something new: fear of making an unfavorable discovery about one's abilities as a result of the change, fear of failing to satisfy the expectations of important others, fear of taking on new responsibilities, and fear of giving up a known present for an unknown future. For many middle adults, the process of career change requires a reassessment of assumptions that were made in adolescence and early adulthood about gender expectations, family roles, and their attached career ambitions. The process of career change involves gaining insights into one's hopes and ambitions as well as the changing nature of the labor market in order to conceptualize a path forward (Markel, 2016).

The ease or difficulty of work transitions depends in part on the extent to which workers perceive that they have control over the conditions of the change. Voluntary transitions usually occur with some control over the timing of the change and the opportunity to prepare financially and to acquire new credentials or skills. What is more, in the case of voluntary work transitions, the person has the sense of agency about making decisions that advance desired goals. Involuntary transitions often occur with little chance to select the optimal time or to save up for the possibility of a period of unemployment or reduced income. There is less opportunity to consider the impact of the transition on family members. The person who is making an involuntary transition may feel compelled to take a position in order to support the family or to meet existing financial obligations even if the position is not a very good fit with personal values or goals (Fouad & Bynner, 2008).

The Impact of Joblessness

Even though the workplace can be a major source of stress, **joblessness** can be even more disruptive to personal mental health and family functioning. As a result of the restructuring of the labor market, plant closings, downturns in the economy, and workforce reorganizations, many workers who had a history of steady employment, including increased responsibility and advancement, have faced job loss in their middle adulthood. Unemployment in middle adulthood has a major psychological impact on an individual's sense of self-worth and hope for the future. Among middle-aged workers, job loss is associated with material deprivation, disruption in family life, and increases in marital conflict.

Al Franken
Democrat for U.S. Senate
Al Franken
Al Franke

miker/Shutterstock.com

Al Franken made a dramatic midlife career change. He left his role as a comedian and ran for the United States Senate. He won a hard-fought contest and has become a respected senator.

Children and spouses are acutely involved in the effects of job loss on a middle-aged parent, and often the entire family experiences new feelings of alienation from social institutions as a result of the experience (Stevens, 2014).

Job loss has been associated with both physical health and mental health consequences, such as self-doubt, passivity, and social withdrawal. Depression is a common consequence, and the associated family strains may lead to new levels of conflict and family violence. In some instances, adjustments that families make to a husband's unemployment result in a further reduction of his sense of importance and accentuate the decline in his self-respect. Social support—especially family strengths and marital satisfaction—are important buffers for the negative effects of unemployment (Bambra, 2010; Blustein, 2008).

In 2004, the U.S. unemployment rate was 4.4 percent, slightly higher for men than for women. The modal period of unemployment was less than 5 weeks, but about 22 percent were unemployed for 27 weeks or more. By the end of 2009, the rate was 10 percent, and 40 percent of those who were unemployed, or 6.1 million people, were long-term unemployed (e.g. had been jobless 27 weeks or more). At the end of July 2016, the unemployment rate had dropped to 4.9 percent among whom 2 million were considered long-term unemployed (U.S. Bureau of Labor Statistics, 2013a, 2016b). An additional 2 million adults were marginally attached to the labor market (they were willing to work but had not looked for work in the last 4 weeks), and another 600,000 were discouraged workers (they were not looking for work because they did not believe there were any jobs available for them).

Table 12.1 summarizes the unemployment rates in 2015 by race/ethnicity and educational attainment for individuals ages 25 years old and older. African Americans and those with less education were at especially high risk for unemployment (U.S. Bureau of Labor Statistics, 2016c).

There is a difference in how people cope with seasonal or short-term (less than 5 weeks) unemployment and long-term or chronic unemployment (Morin, 2010). From 2011 to 2015, 3.2 million workers who had been at their jobs for 3 years or more were displaced from their job because their plant or company closed or moved, there was insufficient work for them to do, or their position or shift was abolished. Although two-thirds of these workers were eventually re-employed, the experience of job loss, job search, and prolonged unemployment was deeply distressing (U.S. Bureau of Labor Statistics, 2016d).

Because of the cultural emphasis on productive work, people are especially likely to experience guilt about being unemployed. Moreover, for men, unemployment disrupts the self-concept of the traditional definition of the adult male role as breadwinner for the family. As a result of guilt, shame, and anger, men may

These blue collar workers have lost their jobs, and they are angry about it. Their jobs have been outsourced to other countries. They do not foresee new jobs that would be right for them emerging in the recovery. They have banded together in an organization through which they are asserting their right to work.

Table 12.1 Unemployment Rates by Ethnicity and Educational Attainment, 2015

	Educational Level			
Race	Less Than High School	High School Graduate	Some College, No Degree	Bachelors Degree or Higher
European American	6.8	4.6	4.4	2.4
African American	15.9	9.7	8.0	4.0
Asian American	5.4	4.1	3.4	2.8
Hispanic/Latino	6.6	5.9	5.3	3.4

Source: U.S. Bureau of Labor Statistics, 2016, Table 7.

find it hard to direct their energy toward creative solutions to life problems. The inability to work can be expected to become a serious hurdle to the resolution of the psychosocial conflict of generativity versus stagnation for men. In a comparison of men and women who had a combination of breadwinner and childrearing responsibilities, the men were more likely to view unemployment as a defeat, whereas the women were more likely to view unemployment as an opportunity (Forret, Sullivan, & Mainiero, 2010).

In a qualitative study of 13 men and women who were unemployed or underemployed, different stories of job loss and coping emerged (Blustein, Kozan, & Connors-Kellgren, 2013). First, some were shocked by the sudden news that they were being laid off whereas others anticipated the possible job loss. Those for whom job loss came "out of the blue" had a harder time reacting to the news and experienced more immediate emotional distress. Second, some saw the reason for their job loss as personal, e.g. they had a long-term illness or they had fewer qualifications than others, while others saw the reason as due to a larger corporate or societal factor, e.g. good jobs are being sent overseas or companies are downsizing to give more money to corporate executives. Third, participants differed in the kinds and levels of support during their unemployment. Some felt a particular loss of social support whereas others had a strong friendship and family support network; some were more severely impacted by financial loss than others; and some found that their physical health prevented them from being considered for new jobs. Those with serious financial limitations also had more limited access to education or training for new kinds of work. Not unexpectedly, participants differed in their ability to cope with the job loss and to redirect toward new work. Some participants were more proactive, networking, volunteering, retraining, and focusing on their own improved physical and mental health. Others suffered with the combined stressors of increased economic insecurity, loss of self-esteem, and anxiety about the uncertainties of future employment.

Aaron has been unemployed for slightly less than 1 year. He is being interviewed at a one-stop career counseling center.

> Being unemployed does humble you. It makes you think, it makes you see things in a different perspective, it makes you test your humanity and how others treat you when you are not working. Cause when I was working I was the hero, you know why? Cause I was paying the bills. I had a home you know, I was able to go to certain places, buy certain things . . . And they said that you had counselors here but a counselor cannot do anything for me. You have a job—what can you possibly do for me that you've got a job . . . And when I leave you, you still have a job. I'm out here hustling the best I can to make sure that I still have a roof over my head and still able to eat and I can still apply myself and get some a little bit of satisfaction in the process. (Blustein, Kozan, & Connors-Kellgren, 2013, p. 262)

The threats of job loss and job insecurity can also create stress for those who remain employed as well as for those who become unemployed. For example, in a study of employment conditions on job-related distress, workers in industries that were experiencing high levels of unemployment had a higher incidence of depression than did workers in industries where unemployment was low. Similarly, studies have shown that workers who are spared during downsizing and mergers show signs of anxiety and depression.

These observations highlight the salience that work has in middle adulthood and the role that meaningful work plays in supporting well-being. At its best, work provides resources for survival, creates a context for social relatedness, and offers opportunities for self-determination. As such, involuntary long-term or chronic unemployment or underemployment can undermine a middle adult's sense of mattering and establish conditions for alienation or self-loathing (Blustein, 2008; Garrett-Peters, 2009).

Balancing Work and Family Life

Almost everyone manages a career while juggling commitments to spouse, children, parents, other household members, and friends. A decision to assume more authority, work longer hours, accept an offer with another company, quit a job, accept a transfer to a new location, or start up one's own business will touch the lives of other household and family members.

In thinking about balancing work and family life, it is useful to consider three interrelated concepts: role overload, role conflict, and role spillover. **Role overload** occurs as a result of too many demands and expectations to handle in the time allowed. For example, a parent with three children ages 8, 11, and 15 may find that the demands of getting the children ready for school, attending functions at three different schools, picking children up and dropping them off at various places, and trying to be emotionally available for the problem of the day are exhausting. Role overload can be experienced within a particular role as well as across roles.

Role conflict occurs when demands and expectations of various roles conflict with each other. For example, role conflict occurs when a worker is expected to stay late at the job to finish a project, but that same night is a spouse's birthday or a child's performance.

Role spillover occurs when the demands or preoccupations about one role interfere with the ability to carry out another role. For example, a person may be disrupted at work by worries about an ill parent or distracted at home by a work assignment that is due the next day.

Role overload in the workplace is consistently perceived as a source of stress and is typically associated with negative attitudes toward the organization, reducing a worker's organizational commitment and job satisfaction (Eatough, Chang, Miloslavic, & Johnson, 2011). Some occupations are more likely to create work overload, especially when companies are downsizing and increasing the demands on a reduced workforce. Studies of role overload are also beginning to address the health-related implications. For example, adults who suffer from arthritis are likely to report that work-related strains can exacerbate their symptoms (Gignac et al., 2014; Mustafa et al., 2012).

Two features of the workplace that are thought to relieve this strain are empowerment in the job and a cooperative workplace climate. **Empowerment** can include strategies to increase a sense of job control, such as opportunities to be creative and innovative in one's work, to have a role in decisions that impact how one performs one's work, and to be encouraged by one's supervisor to have adequate authority about how to get one's job done. A cooperative climate reflects a spirit of teamwork and collaboration among coworkers who are willing to help one another to get the job done (Fisher, 2014). In a large, cross-national study involving workers in 18 countries, the negative relationship between role overload and organizational commitment was observed across all contexts. A cooperative climate was found to modify this relationship. However, a sense of empowerment was only effective in cultures that had a more egalitarian work climate. In cultures where the power distance between supervisors and workers was great, the institution of workplace empowerment practices did not ease the tensions around overload (Fisher, 2014).

The combination of role overload, role conflict, and role spillover can lead to reduced satisfaction at work and in family roles and a decline in the person's sense of well-being (Kinnunen, Feldt, Mauno, & Rantanen, 2010). However, some studies find that multiple role involvement may contribute to health and well-being. Spousal support for the partner's involvement in work can increase work satisfaction, and feelings of success and pride in one's accomplishments at work can contribute to marital satisfaction (Dreman, 1997). In a large, longitudinal study of British women born in 1946, those women who had participated in multiple work and family roles over the course of their adulthood were healthier at age 54 than women from the same birth cohort who were long-time homemakers (McMunn, Bartley, Hardy, & Kuh, 2006).

The domains of work and family, both central to adult lives across cultures, are likely to conflict under certain circumstances and complement each other in other circumstances. In order to understand the nature of this relationship, researchers have identified the elements of work and the elements of family life that appear to be most central to this conflict. A model of how job characteristics and family characteristics might contribute to work–family conflict and family–work conflict is presented in FIGURE 12.1 ▶.

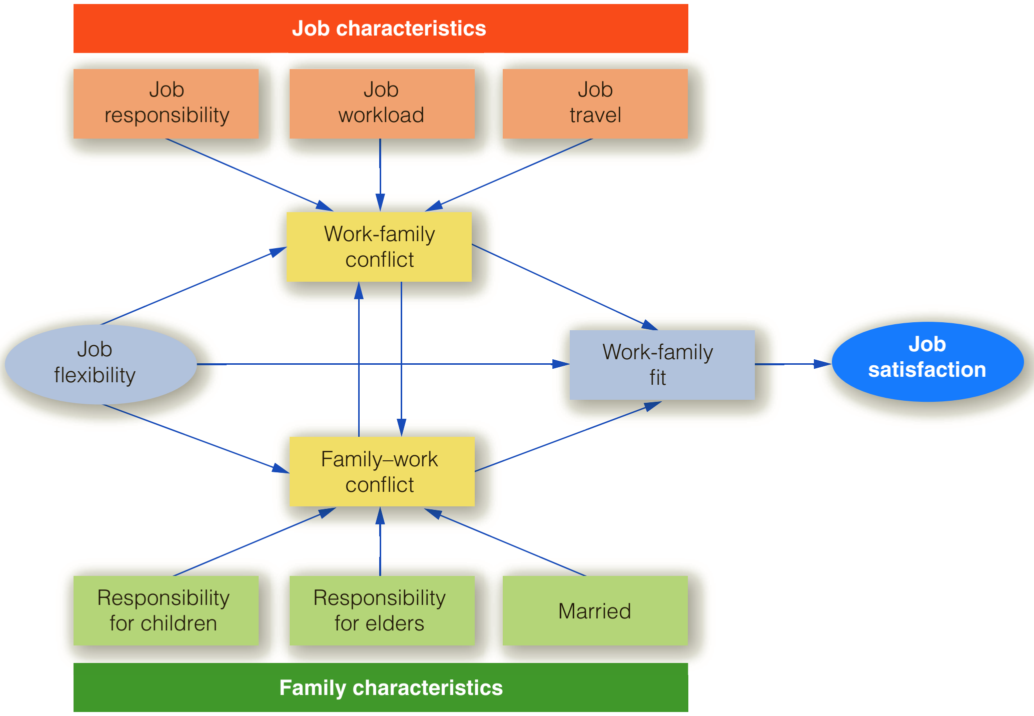

FIGURE 12.1 ▶ A MODEL OF THE WORK–FAMILY INTERFACE

Source: Hill, Yang, Hawkins, and Ferris, 2004, Fig. 1, p. 1302.

The basic assumption is that there are role pressures from work and family that are mutually incompatible, so that meeting the expectations in one domain makes it very difficult to meet expectations in the other. Moreover, there may be interactions such that conflicts from work make it difficult to meet role expectations in the family, but then the disruptions in the family make it difficult to meet role expectations at work (Greenhaus & Allen, 2011). Despite these tensions between work and family obligations, people strive to find ways for the two roles to work together (work–family fit), which leads to greater job satisfaction. Job flexibility, for example, a workplace policy that supports taking hours off to carry out family-related responsibilities, is one factor that can contribute to this successful adaptation.

The model presented in Figure 12.1 was tested in 48 countries (Hill, Yang, Hawkins, & Ferris, 2004). The characteristics of a job that were hypothesized to produce work–family conflict were job responsibility, job workload, and job travel. The characteristics of the family that were hypothesized to produce family–work conflict were responsibility for children, responsibility for elders, and being married. The model was tested by analyzing survey responses of more than 25,000 IBM workers whose average age was 39. The countries were divided into 11 Eastern countries with a collectivist orientation, and three groups of countries with a more individualist orientation: Western developing countries, Western affluent countries, and the United States.

The model was a good fit for all four groups of countries. The three job characteristics were significantly related to work–family conflict across all 48 countries, although the strength of the relationship was greater in the three individualist groups of countries. Responsibility for children and elders was related to family–work conflict across all the countries, but this relationship was stronger for women than for men. Contrary to expectations, marriage was related to less family–work conflict across all the countries. Job flexibility was associated with less work–family conflict in the Eastern countries and the Western developing countries, but not in the Western affluent countries or the United States. Across all the countries, work was much more likely to create conflict in family life than family life was to be disruptive for work. The general model was a good predictor of job satisfaction across these very different work environments. One might ask whether the global corporate environment of IBM might have smoothed out some of the cultural variations that would have been observed had workers been drawn from a greater diversity of businesses. However, this research is a very exciting approach in trying to understand the dynamics of work–family interactions at a global level.

This cross-national study also adds to a growing literature documenting that women are more distressed by family–work conflict than are men, possibly because responsibilities for household and child care continue to rest more on the shoulders of employed women than on those of employed men (Voydanoff, 2004). Nonetheless, trends in the United States are moving toward a more egalitarian model. Men and women increasingly agree on the value of having women in the labor market and the importance of family-friendly workplace policies. Employed men are spending an increasing amount of time on household and child care tasks, both on workdays and nonworkdays.

Balancing work and family life is challenging; it involves the interface of multiple, interacting systems—each partner's work environment, each partner's role demands within the family, and the partners' relationships with one another and with their children. Over time, the partners adapt to the changing demands of the workplace by modifying their involvement in household tasks. As adults become increasingly invested in their work, they may do less household work. If one partner becomes more involved at work, the other partner may take on more of the household responsibilities (Lam, McHale, & Crouter, 2012). One study found that for professional couples with children, when husbands were required to work long hours at their job, the probability of the wife quitting her job increased (Cha, 2010).

Work conditions involving high demands and little support have an impact on parents and their children. Mothers who worked long hours and felt overloaded were less warm and accepting toward their adolescent children. Fathers who worked long hours and felt overloaded experienced more conflict with their adolescent children. Husbands' negative work-related stressors also increased their wives' sense of overload beyond what the wives were experiencing because of their own work situation (Crouter & Bumpus, 2001). When either partner experiences a lot of work pressure, multiple role demands and little support from the boss or supervisor, the impact on the couple and the family is negative. Under these conditions, adults have more marital conflict, less quality time for each other, and more conflict with their adolescent children (Ransford, Crouter, & McHale, 2008).

When couples have a shared view of one another as co-providers who contribute equally to their economic and personal well-being, they tend to experience less stress associated with role overload and higher levels of marital satisfaction (Helms, Walls, Crouter, & McHale, 2010). Ellen Galinsky (2007) has coined the term *dual-centric* to describe people who put the same emphasis and priority on their work and their personal lives. These people are equally likely to be men and women. They are more likely to have children at home, and they spend an average of about 5 hours a week more at home than those who place a higher priority on work than on their personal lives. These dual-centric individuals feel more successful at work and at home, and by objective measures, such as their level in the organization or their salary, feel equally successful as those who place a greater priority on their work. In comparison to those who place a higher priority on either their work or their personal lives, dual-centric people experience lower levels of stress, and fewer say that they find it difficult to manage their multiple roles. These dual-centric adults were very clear and intentional about having both domains as priorities in their lives, they set some clear boundaries between the domains, they practiced being emotionally as well as physically present in the sphere where they were functioning at the time, and they took time to rest or redirect their energy away from work from time to time.

JDC/Corbis/Getty Images

After the birth of her twins, Karen decided to try working from home. She balances work and family life by having a babysitter 3 half days and trying to work on small projects for a half hour here and there while the twins are awake. The twins love their mom's computer and are eager to help.

Although much of the responsibility for managing multiple roles falls to individuals and couples, **work–family facilitation** can be supported by resources in the workplace that make it easier for employees to address pressing family demands within the scope of their daily work (Voydanoff, 2004). When the workplace is organized to recognize and sustain the multiple-role responsibilities of employees, people are likely to experience an increase in their sense of self-worth, competence, and fulfillment, resulting in a more positive outlook on their interpersonal relationships at home and greater productivity at work. These policies are often referred to as supporting "work-life fit." Some examples include policies that allow workers to take family-related leaves without risking their job security, to take time off during the day to take a child to the doctor or meet with a teacher, or to focus on work accomplished regardless of where it is done as opposed to hours at the office. A supportive work climate in which supervisors help workers feel comfortable about using these flexible policies and accommodating significant personal obligations contribute to work–family facilitation. Given that most people in middle adulthood are expected to be functioning in multiple roles, it makes sense that the responsibility for success in achieving an effective balance between work and family demands should rest not only on the coping strategies of individuals and couples, but also on the policies and climate of the work setting, and the practices of managers and supervisors (Kelly et al., 2014).

FURTHER REFLECTION: *Summarize how the demands of managing a career change from early to middle adulthood.*

Describe some of the conditions that have occurred over the past 25 years that have changed the work environment for American workers. What are your conclusions about the implications of these changes for development in middle adulthood?

What characteristics of the work environment are most likely to foster intellectual growth, job satisfaction, and the ability to effectively balance work and family life? How common are these characteristics for jobs at the top, middle, and bottom of the economic ladder?

How does home life facilitate or interfere with job performance for men? For women?

Nurturing an Intimate Relationship

OBJECTIVE 2 Define the concept of a vital, intimate relationship and examine factors that support this goal in middle adulthood, especially a commitment to growth, effective communication, creative use of conflict, and preserving passion.

Although people derive a significant sense of personal identity from their jobs and may worry a lot about them, happiness in an intimate relationship is a stronger predictor of overall well-being in adulthood than is satisfaction with work. According to a survey conducted by the AARP (American Association of Retired Persons, 2010), over 90 percent of men and 86 percent of women in middle adulthood reported that having a good relationship with a spouse or partner was very important to their quality of life. Marriage and other long-term intimate bonds are salient, dynamic relationships. They change as the partners mature, as the family constellation changes, and in response to changing events, including divorce and remarriage, family crises, and historical events. Focus and effort are required to keep these relationships healthy and vital throughout middle adulthood.

What is a **vital marriage**? Four themes have been identified as contributing to long-lasting, happy marriages: the characteristics of the individual partners, the nature of the partners' **interpersonal interactions**, the partners' commitment to nurturing the future of the relationship, and the preservation of passion in the relationship (Crooks & Bauer, 2010).

Characteristics of the Partners

Happy marriages are built on love and affection between two people who are basically even tempered and warm hearted (Huston & Melz, 2004). Continuing ego development and adaptive restructuring of personal identity in the context of meaningful social roles provide a core of personal strengths that help sustain interdependence and care in the face of the many challenges of middle adulthood (Marcia, 2002, 2010). The partners in a vital marriage are not overly anxious, depressed, or impulsive. They are nurturing, expressive, gentle, understanding, and conscientious. They care about each other, rather than being self-absorbed or indifferent to one another's fate.

These individuals also contribute other types of social capital that help sustain the relationship. For example, they may have a supportive network of family members and friends, they may contribute financial resources to the family, they are cooperative rather than domineering in the way they participate in decision making, and they bring unique competencies to the tasks of household maintenance (Edin, 2000).

Early childhood trauma, especially childhood sexual, emotional, and physical abuse, have been found to derail the capacity for sustaining close, trusting adult relationships (McCarthy & Sypeck, 2003). Adults who were abused as children report fear of intimacy, dysfunctional sexual behaviors, strong feelings of jealousy, and patterns of re-enacting earlier abusive relationships with contemporary partners. Symptoms of post-traumatic stress disorder continue to arise, which result in dissociation and self-criticism (Davis, Petretic-Jackson, & Ting, 2001; Liang Williams & Siegel, 2006). Many first person accounts suggest that adults who have had repeated abusive relationships eventually give up on intimacy and prefer to live a more peaceful life without a partner. As the following narrative suggests, it is possible to find a secure, loving relationship, but it may take a special partner (Buczynski, 2016).

> I experienced trauma as a child through being adopted into a family where my parents were themselves dealing with trauma (dad from the war). I was a very insecure child. I can remember my mother telling me I had an "inferiority complex". She was authoritative and we clashed later in life. I married at 18 to a violent man and spent the next 18 years dealing with that—by this stage I argued back and on the surface I seemed confident, but I was very self-critical inside. After the marriage ended, I had a series of same-sex relationships in which I was described as emotionally volatile—I worked hard at being wanted—it was exhausting. I am now in a relationship of 12 years and until recently I pushed my partner away, always planning to escape especially when we argued. It seemed like a trigger—if I went to my "cubby" everything would be alright. My partner is steadfast and would not give up on me. Something recently changed in me (I had exhausted all my escape plans perhaps) and I am able to truly commit to the relationship. I feel safe. I feel as if I belong here. The peripherals are not important anymore. (first person narrative comment from Helen, in Buczynski, 2016)

Partners' Interpersonal Interactions

Long-term stable relationships are typically based on a strong bond of friendship. The partners support each other and like each other. They have shared interests, enjoy similar activities, and are supportive and appreciative of one another's accomplishments. The couple must develop an effective communication system. This requires adequate opportunities for interaction. If competing life roles, including work and parenting, dramatically reduce opportunities for interaction, the couple will risk drifting apart. They will have increasingly fewer shared experiences and be less readily influenced by each other's observations and reactions. There is a reciprocal relationship between interaction and happiness. In a longitudinal study, couples who were happier early in their marriage showed higher levels of interaction in later years (Zuo, 1992). After a number of years of marriage, the two variables were strong predictors of each other: Those who were happy were involved in more frequent interactions, and, similarly, those who were involved in frequent interactions were happier.

John Gottman and his colleagues have examined the nature of interactions among heterosexual married couples. Based on their research, they have been able to predict with a high degree of accuracy whether couples will separate in the first few years of their marriage or stay together (Driver, Tabares, Shapiro, & Gottman, 2012; Gottman, Coan, Carrere, & Swanson, 1998; Gottman & Silver, 2000). Enduring relationships are characterized by a high ratio of positive to negative interactions. Couples

Monkey Business Images/Shutterstock.com

Omar and Vidya have been married for 10 years, and they have two young children. He works as a field agent for the gas company. She works from home as a copywriter for a catalog company. This allows her to devote time and attention to caring for the children and managing the household. They are still deeply in love and delight in sharing a few moments to cuddle and laugh together.

in satisfied marriages did argue, but the balance of five positive statements to one negative statement was an important constant in predicting relationship stability. In stable, satisfied heterosexual couples, the woman tends to use a gentle, diplomatic beginning when she introduces a problem or concern, and the man accepts his wife's influence. When the woman expresses contempt, is overly negative, or aggressive and the man is overly domineering or defensive in the face of conflict, the relationship is less likely to endure.

Do men and women have different ways of expressing their love? In many ways, men and women are alike in the ways they express affection and in the importance they place in trust as a component of a loving relationship. Couples have many personal and private ways of conveying their love—a joke, a caress, a look, a word or expression that captures a shared experience, the preparation of a special dish. When observed in day-to-day interactions, some differences have also been found. Women show their love through their positive interactions, expressing less whining, complaining, or criticizing of their husbands. Men show their love by initiating lovemaking, participating in shared leisure time activities, and joining their wives in carrying out daily household work (Schneider, Konijn, Righetti, & Rusbult, 2011; Schoenfield, Bredow, & Huston, 2012).

For couples that do not have an effective communication system, resentments accumulate with no opportunity to resolve them. A common pattern is that the wife wants to talk things over, but the husband does not see what good this will do. Harmonious, satisfied couples listen to and consider each other's problems. They validate each other's concerns by expressing understanding, even if they cannot offer solutions. In contrast, dissatisfied couples avoid problems or engage in counterattack. Instead of validating the spouse's concern, the partner raises complaints and criticisms or withdraws. Over the years, expressions of affection, enjoyment, laughter, and support decline. Even if negative or critical interactions do not increase, they are embedded in a less positive overall context. The ideal 5 to 1 ratio may drop to 3 or 2 to 1, making the negative interactions more salient. This takes the couple along the path to marital disruption.

Partners' Commitment to Nurturing the Future of the Relationship

In order for a marriage to last over the long period of middle and later adulthood, the partners have to see a long-term commitment as one of their values. Research on cohabitation and research on marriage stability among children whose parents divorced both illustrate contexts in which adults may view marriage as a more temporary alliance than as a lifelong relationship. Assuming that couples share a view of their relationship as long term, the partners must learn to work toward change in areas where it is possible and to accept one another and the characteristics of the relationship in areas where change cannot be accomplished. By expanding their tolerance for differences and admiration for their strengths, couples can achieve new levels of intimacy. Research on long-lasting, satisfying marriages identified a set of psychosocial tasks that couples have to master (Wallerstein & Blakeslee, 1995). Salient in this list are the following challenges:

- Preserving a balance between intimacy in the couple and autonomy for the individuals
- Expanding the bonds of affection to include children while preserving and nurturing the couple relationship
- Shifting the focus of energy from the family of origin to the newly formed family while preserving relationships with the extended kinship network
- Managing the adversities in life, such as serious illness, death, or disaster, in ways that strengthen the relationship
- Sharing laughter and delight in daily life

The partners must be committed to growth both as individuals and as a couple. This means that they accept the idea that they will change in important ways and that the relationship, too, will change. Within any enduring relationship, each person experiences a dynamic tension between pressures and desires for personal growth on the one hand and the pressures and desires to preserve the relationship on the other hand. Both of these forces have the potential to overwhelm or dominate the sense of mutuality, as is illustrated in the case study on the struggle for commitment to growth in a vital marriage. A vital marriage requires both partners to be open to the need to be themselves (as they continue to discover new dimensions of self) and an energizing, interpersonal chemistry that is resilient even in the face of the harshest challenges. Partners in an enduring relationship repeatedly act in ways that take into account their own self-interest and the well-being of their partner (Rusbult & Agnew, 2010).

— **CASE STUDY** The Struggle for Commitment to Growth in a Vital Marriage —

One common example of the need to permit individual growth within a marriage occurs when a woman who has been primarily responsible for child care and household management expresses an interest in entering or returning to the paid labor force.

Annette, who had worked as a nurse before she married, decided that it was time to go back to work. Her three children were in elementary and middle school, and her husband had a full-time job, so she was by herself for long hours during the day. She began to feel depressed and jealous of everyone else's active lives, so she took a position at a local hospital, working three afternoons and on Saturday each week.

At first, her husband, Gary, fussed and resisted. "Why did she need to go to work?" he asked. They didn't really need the money, and Gary liked to know that she would be at home when he came back from work. He wasn't used to having to take the kids to their activities after school. Plus, Saturday used to be his day to hang out with his friends from work. The kids fussed at being asked to get dinner ready. But Annette insisted that she had to get back to work—her mental health and happiness depended on it.

The first months were terrible. Annette wondered if she was doing the right thing, and Gary used every trick in the book to lure her back to the house. But there was no denying the value of this new job for Annette's self-confidence, her renewed feeling of personal identity, and her ability to return to the home with new energy and enthusiasm for her husband, children, and family life. Gary began to get more involved in the children's lives and actually looked forward to the Saturdays they spent together. Soon the children began to see their mother in a new light, as a professional who took care of other people as well as them. They also felt a new surge of independence in being able to handle the dinner meal on their own. Gary and Annette felt closer to each other as a result of Annette's self-confidence and Gary's new level of involvement in the lives of the children.

CASE ANALYSIS Using What You Know

1. Summarize the features of a vital marriage that are evident in this case. What features of a vital marriage are missing?
2. Describe the changes in the family system that take place from Annette's initial decision to return to work to the eventual pattern of family adaptation.
3. Explain how Annette's decision leads to new opportunities for growth for Gary, her children, and herself.
4. Imagine that Gary had been the one looking for a new structure—perhaps going into business for himself or going back to school for a new profession. What types of changes might this have caused in the family system? On the marital relationship?

Preserving Passion in a Long-Term Relationship

According to Sternberg's three-dimensional model of love presented in chapter 11, passion is the first thing to go. However, preserving an erotic and sexual aspect to intimacy continues to play a role in fostering long-term **intimate relationships** throughout adulthood. Relationship satisfaction is associated with openness about sexual needs, satisfaction with sexual frequency, and experiencing a playful enjoyment of sexual pleasure (Crooks & Bauer, 2016). This means coping with the physiological changes in sexual responsiveness that accompany aging and finding new ways to enjoy sexual contact in the context of parenting demands, chronic illness or disability, or other stressful life events that interfere with one's sexual interest. Results of an AARP survey found that having a satisfying sexual relationship was somewhat more important to men than to women in middle adulthood. However, for both men and women, those who had a satisfying sexual relationship had higher life satisfaction than those who did not (AARP, 2010).

Changes in sexual responsiveness over the middle adult years have been well documented (Crooks & Bauer, 2016; Masters & Johnson, 1966). For men, erections take longer to develop, orgasm is less intense, and the erection fades more quickly. With age, it may take a longer period, from several hours to days, to experience a new erection. Even though the sexual response changes, orgasm continues to be a source of pleasure. Although there is a reduction in sperm production, most men remain fertile well into elderhood. Most men are able to enjoy sexual activity throughout their life provided they continue to have a partner.

For some men, periods of illness, certain medications, heart disease, or high blood pressure can interfere with the ability to have an erection. Anxiety about being able to have an erection or a preoccupation with the quality of sexual performance may interfere with the ability to become aroused. The availability of drugs to treat erectile disorders has increased openness and awareness of this problem and provided new avenues for couples to discuss changes in their sexual vitality. An estimated 18 million men age 20 and older in the United States have erectile dysfunction (Selvin, Burnett, & Platz, 2007). Although the incidence increases with age, usually it is not age itself, but illnesses that are associated with aging and the accompanying medications that account for this relationship.

One of the common changes experienced by men in midlife is inflammation or increased size of the prostate gland. This gland produces fluids that are released during ejaculation. When the prostate becomes enlarged, it may put pressure on the urethra and restrict the flow of urine. A significant number of men experience prostate cancer. Although treatments for prostate cancer vary, they can interfere with sexual functioning (Ofman, 2004).

Physical changes that affect the sexual response also occur for women. At some time during their late 40s or in their 50s, women experience the **climacteric**, or the involution and atrophy of the reproductive organs. Many physiological changes accompany the close of fertility, including the cessation of menstruation (**menopause**), gradual reduction in the production of estrogen, atrophy of the breasts and genital tissues, and shrinkage of the uterus (Carroll, 2012). The most commonly reported symptom is a frequent hot flash, a sudden onset of warmth in the face and neck that lasts several minutes. Sometimes it is accompanied by dizziness, nausea, sweating, or headaches. About 75 percent to 85 percent of women going through natural menopause report this symptom. Other physiological symptoms are the reduction of vaginal fluid and loss of elasticity, sleeplessness, and increased anxiety (Nelson, 2008). The symptoms appear to be closely related to a drastic drop in the production of estrogen. Postmenopausal women produce only one sixth as much estrogen as do women who regularly menstruate.

The use of estrogen treatment alleviates or even prevents menopausal symptoms. Results of research from the Women's Health Initiative found a relationship of hormone replacement therapy to decreased risk of osteoporosis, cardiovascular disease, and colorectal and lung cancers, but an increased risk of breast cancer. As a result, many physicians have stopped prescribing hormone replacement therapy and have begun to seek alternative therapies to help reduce severe symptoms of menopause for those women who experience them (Beck, 2008).

The reduction in estrogen is associated with changes in the sexual response cycle. The most noticeable change is decreased lubrication and less expansion of the vagina during the excitement phase. This can cause pain during intercourse and reduced sensitivity, which interfere with sexual pleasure. Although the number of orgasmic contractions may be fewer, orgasm remains a pleasurable experience for postmenopausal women. Without the risk of pregnancy, many women are more enthusiastic about sexual relations after menopause than they were before. As discussed in the **Human Development and Diversity** box Menopause, the

HUMAN DEVELOPMENT AND DIVERSITY

Menopause

The experiences associated with menopause differ widely from one person to the next. The severity of symptoms is associated with both the biological changes related to decreases in estrogen production and the attitude of the culture toward the infertile, older woman. In cultures that reward women for reaching the end of the fertile period, menopause is associated with fewer physiological symptoms. In a study describing the reaction of women in India, menopause was associated with increased social status: "The absence of menstrual flow signaled an incredible elevation of stature for these women. Women were released from a veiled, secluded life in a compound to talk and socialize (even drink) with menfolk. They then became revered as models of wisdom and experience by the younger generation" (Gillespie, 1989, p. 46). Women from different cultural groups have diverse attitudes about menopause that may create a more or less positive context for the end of the reproductive stage of life (Lerner-Geva, Boyko, Blumstein, & Benyamini, 2010).

Within a society, a woman's attitudes toward aging and her involvement in adult roles influence the ease or difficulty with which she experiences menopause. In U.S. society, for example, a woman who is going through menopause at age 50 may also be experiencing the severe illness or death of her parents and the marriage of her youngest child. The severity of menopausal symptoms and the extent to which women experience changes in their sexual motivation may depend largely on their involvement in a satisfying intimate relationship (Hinchiff, Gott, & Ingleton, 2010).

In the U.S. medical culture, the tendency is to view menopause as a normal developmental transition associated with symptoms that can be alleviated with various hormonal and dietary supplements. Many publications dealing with menopause focus on issues such as the treatment of symptoms and the pros and cons of hormone replacement therapy (Womenshealth.gov, 2010). Comparatively few studies have focused on the social and psychological correlates of menopause.

Women differ in how they interpret the meaning of menopause. Some are embarrassed by the hot flashes when they occur in a public setting. Others see the symptoms of menopause as a reminder that they are aging in a culture that values youth and physical attractiveness in women above other characteristics. An emerging group has recast hot flashes as *power surges*, suggesting the beginning of a new, competent period of life.

In an online survey, women from four ethnic groups were asked to describe their menopausal symptoms (Im, Lee, Chee, Dormire, & Brown, 2010). Asian American women reported the fewest symptoms; European American women reported the most. Among African American women, there was a cultural theme of being strong, accepting menopause as a natural process, and keeping silent or downplaying their symptoms. Individual variability was noted, with sensitivity to symptoms linked to the woman's health and concurrent life stressors, as well as her cultural beliefs about the meaning of this transition in her life.

The North American Menopause Society (NAMS) provides resources to address women's concerns about menopause. Health-related issues, including concerns about weight gain, osteoporosis, sleep disturbances, and sexual dysfunction are associated with the hormonal changes of menopause. Many women are frustrated by the lack of clear information they receive from their health care providers. At the same time NAMS advises women to see this transition as a stimulus for new beginnings, a time to take a closer look at one's health, one's relationships, and one's investment in satisfying activities (North American Menopause Society, 2013, 2015). They note the similarities between menopause and puberty as significant biopsychosocial transitions, except that with menopause most middle adults have the advantage of life experience to shape the direction of their development.

For more information about menopause, see the North American Menopause Society website and the National Institute on Aging.

Critical Thinking Questions

1. How does menopause relate to the developmental tasks of middle adulthood?
2. Talk to three or four women who have not yet experienced menopause and three or four who have experienced menopause. Summarize the factors that account for differences in the ways that women interpret the meaning of menopause. What factors are most likely to be associated with a positive transition?
3. Design a study that focuses on either the psychological or social correlates of menopause. What are your research questions? What might be some difficulties in doing research on this topic?
4. Examine the medical culture in the United States. What challenges do women face in striving to gain information about menopause and their health in a culture that is hierarchical, male-dominated, and heavily influenced by the profit motive of pharmaceutical and insurance companies?

impact of menopause for women is determined in part by its cultural meaning. As with other aspects of an intimate relationship, preserving the sexual dimension requires good communication and a sense of humor.

Nurturing vitality in an intimate relationship is relevant for the ongoing social support it provides as the couple enters later life. What is more, the quality of the parents' marital relationship during middle adulthood has significant consequences for the well-being of children in the family and provides the context for the children's emerging understanding of intimacy and marital roles. As children mature into middle childhood and early adolescence, they pay attention to and try to make sense of the quality of their parents' interactions with each other. As children observe their parents, they acquire a sense of how they function as intimate partners as well as parents. Of course, children will not perfectly replicate their parents' marriages. However, the degree of egalitarianism, the approach to conflict resolution, and the expression of affection that children observe can influence their ideas about the kind of partner they seek, their ability to manage conflict in an intimate relationship, and their expectations about marital interaction (Schulz, Pruett, Kerig, & Parke, 2010).

FURTHER REFLECTION: *Clarify your assumptions about the quality of intimate relationships in middle adulthood. How does the evidence you have read confirm or disconfirm these assumptions?*

Describe how a couple might work to preserve a vital intimate relationship in the face of other competing demands and stressors of adult life.

Speculate about alternative outlets for experiencing intimacy for adults who do not have a life partner.

Expanding Caring Relationships

OBJECTIVE 3 Evaluate the expansion of caring in middle adulthood as it applies to two specific roles—that of a parent and that of an adult child caring for one's aging parents. Clarify your assumptions about the costs and benefits of enacting these roles.

Middle adults have opportunities to express caring in many roles. This section focuses on two of those: parenting and the care of one's aging parents. Both domains offer numerous challenges to the intellectual, emotional, and physical **resources** of the adult caregiver. Beyond family roles, middle adults may also express their caring through charitable giving, a wide variety of careers in caregiving, volunteerism, community action, care of ill or disabled friends and family, foster care, and support of religious and charitable organizations.

Parenting

In parenting, we see the critical intersection of adult development and child development. As parents, adults bring a psychosocial history of ego strengths and core pathologies, coping skills and defenses, and adequate or inadequate resolutions of previous psychosocial crises to the task of nurturing their children. They have scripts from their own childhood, modified by information from friends, relatives, and experts about how to approach the task. With all this, they have to adapt to the unique temperament, developmental level, and strengths or vulnerabilities of each of their children and to the work, family, cultural, and community contexts in which childrearing is taking place.

Parenting takes place over a long period of time. In a two-parent family, the partners have many opportunities to observe and appreciate each other's approaches to the care, nurturing, and guidance of their children. The concept of a **parenting alliance** captures the importance of the working relationship between the partners as they engage in parenting behaviors. The parenting alliance is defined as "the capacity of a spouse to acknowledge, respect, and value the parenting roles and tasks of the partner" (Cohen & Weissman, 1984, p. 35). The parents' personalities, their attachment orientations, the quality of their shared parenting activities, and the infant's temperament all contribute to the quality of this alliance (Goldiolo & Roskam, 2016). It is not surprising that there is a close association between marital satisfaction and the formation of an effective parenting alliance (Hughes, 2006). As adults establish their parenting alliance, they benefit from knowing that their partner values, trusts, and respects the way they enact their parenting role. The confidence and sense of appreciation that come with this knowledge help adults engage more joyfully in their parenting and weather periods of stress. It also provides a context of reassurance for children who observe the way their parents encourage and sustain each other (Hughes, Gordon, & Gaertner, 2004; McHale, Kuersten-Hogan, & Rao, 2004).

Being a parent is a difficult, demanding task that requires a great deal of learning. Because children are constantly changing and are often unpredictable, adults must be sensitive and flexible in new situations in order to cope successfully with their demands. Each period of the child's development calls for new and innovative parenting strategies. Childrearing experiences are different with each child, and the changing family constellation brings new demands for flexibility and learning. With each successive child, however, there seems to be less anxiety about parenting skills. Children help adults learn about parenting through their responses to their parents' efforts and their own persistence in following the path of development.

Fathering

In the history of the field of family science, the research on parenting has focused almost exclusively on mothers. Most research involved interviews or surveys of mothers, and even when the study used the term *parent,* the informant was typically a mother. In an effort to balance this one-sided view of parenting, a growing literature is clarifying the multidimensional nature of the father role and fathering in middle adulthood (Pleck, 2010). Paternal involvement has been characterized along a variety of dimensions, including how men perceive their connection with their children; the frequency and nature of their one-to-one interactions with their children; their responsibility for specific child care needs, such as taking children to school, caring for them when they are ill, or helping with homework; and their accessibility when the child wants to initiate interactions. Research has also focused on men's views and values regarding fatherhood, the impact of fathers on children, and the relationship of marital quality to men's competence as fathers.

Most men find personal meaning and emotional support in their roles as husband and father (Palkovitz, Trask, & Adamsons, 2014). When men were interviewed about their experiences of divorce, many expressed deep grief over the loss of contact with their children. For example:

> For Tim Scott, 49, the hardest part of his decision to end his marriage to his wife, Jane, a doctor, was what would happen to his relationship with his son Robert, then three. "I know I'd miss him. I didn't realize how much. . . . I don't think I realized quite how strongly

> I identified with myself as being a husband and father until it wasn't there anymore. I was absolutely poleaxed by losing Robert, by not having the day-to-day relationship with him." (Cavendish, 2013)

For many men, the positive quality of their marital and parental roles helps them cope more effectively with the stresses of work (Palkowitz, 2002). In many instances, specific lessons from home—including the patience and communication necessary to be an effective parent, willingness to plan and work out alternative strategies for managing daily tasks with his wife, and the admiration he has for his wife in her paid labor force activities—actually help a man function more effectively at work.

In some families, fathers face a particularly difficult challenge in finding time to interact effectively with their children. For example, one naturalistic observational study focused on the quality of family interactions in dual-earner families when parents returned home from work and in the evening when everyone was at home. Fathers typically returned home from work later than mothers. When mothers came home from work, they were usually greeted positively by their children who filled them in on the day's activities. When fathers returned from work, they were greeted positively, but often the children then resumed their activities and little conversation took place about the events of the day. Over the course of the evening, mothers were more likely to spend time with their children; fathers were more likely to spend time alone (Campos, Graesch, Repetti, Bradbury, & Ochs, 2009). One can infer from this pattern that fathers who want to have a more detailed picture of their children's daily lives may have to develop deliberate strategies for engaging their children in conversations when they are together.

In many families, fathers perceive that they are in a "secondary" role during the period of pregnancy and early infancy, especially while mothers are breastfeeding (Datta, Graham, & Welling, 2012). However, as children get older, fathers and mothers modify their caregiving roles. Fathers tend to become more involved in their children's care, and mothers' involvement decreases somewhat. This is especially true when there are more boys than girls in the family. The more hours mothers work, the more responsibility fathers have for their children. Within the context of a loving marital relationship, the traits associated with a competent, caring parental role are learned and practiced so that fathers become increasingly involved and attuned to their child's needs (Bradford & Hawkins, 2006; Jacobs & Kelley, 2006; Wood & Repetti, 2004).

Many children grow up in families where there is no father living in the household. This may be a result of divorce, cohabiting couples who have children and then break up, or unmarried women who have children. A growing literature in child development provides evidence of the important role that fathers can play in the lives of children. As a result, there is a new appreciation for the establishment of **coparenting**, a respectful relationship in which parents who are not living together encourage active involvement with their children. This is in direct contrast to the pattern of parental alienation observed in some couples where one parent, typically the mother, deliberately tries to undermine the attachment relationship of the child to the other parent. Support and encouragement for coparenting is especially important for the continuing engagement of nonresidential fathers who face many barriers to positive involvement with their children (Fagan & Palkovitz, 2011; Palkovitz, Fagan, & Hull, 2013).

Developmental Stages of Families

At each stage of a child's life, the demands on parents change. Infants require constant care and attention. Preschoolers require educational toys and interaction with peers. They can spend a great deal of time in independent or peer play, but they require close, mindful supervision. Early and middle school-age children require parental reassurance about their skills, talents, and fears. Early adolescents require less in the way of physical care but need continuing emotional support and guidance. They pose new financial demands, and they need help clarifying academic and personal goals, and support to foster participation in athletics, after-school activities, peer relations, and social life.

In the following discussion of parenting, we consider the potential influences of the phases of family development on adult development. This approach illustrates the links in psychosocial development across generations. Parents monitor and assess how their children are doing; they continually evaluate their children's struggles, their successes and failures. The more engaged parents are in the parenting process, the more their own well-being is likely to be linked to their perceptions of how their children are faring. When the children are adults, the parents' assessment of their children's health, happiness, and success in life have a direct impact on their own sense of personal fulfilment (Fingerman, Cheng, Birditt, & Zarit, 2012). Parenting highlights the processes through which the development of children may prompt new growth among parents. Although middle adults might be parenting children of any age, we focus on the following four periods that correspond to the most likely transitions that take place as parents age from 34 to 60:

1. The years when children are in early and middle childhood.
2. The years when children are adolescents.
3. The years when children are adults.
4. Grandparenthood.

The Years When Children Are in Early and Middle Childhood. School-age children tap parents' resources for ideas about things to do, places to go, and friends to meet. They seek new experiences in order to expand their competence and investigate the larger world outside the home. The role that parents play in exposing their children to cultural resources, such as music, art, travel, theater, and science, contributes positively to the children's school achievement, even beyond the impact of the parents' own educational background, beliefs, and expectations (Roscigno & Ainsworth-Darnell, 1999). Parents become active as chauffeurs, secretaries, and sometimes as buffers between their children and the rest of the community.

During this time, parents have many opportunities to function as educators for their children. They actively contribute to their children's academic success through such activities as reading with them, helping them with homework, praising them for school success, and school involvement, including talking with teachers, visiting the school, participating in school projects, or joining school committees. Research on academic success makes it clear that parents' aspirations for their children, their overall parenting skills, and their involvement in their children's education make a substantial contribution to their children's progress (Gutman & Midgley, 2000). Parents who combine appropriate challenges with warmth and support typically have children who are highly motivated, think of themselves as academically capable, and want to do well in school (Bronstein et al., 1998). Parents of early and middle school age children typically believe that they are responsible for their children's school performance, and they want their friends, family, and community members to think well of them in their parenting role (Pew Research Center, 2015).

Parenting during this period has the potential for boosting an adult's sense of pride in the skills and knowledge already accumulated. Parents are gatekeepers to the resources of the community. They come to see themselves through their children's eyes, as people who know about the world—its rewards, treasures, secrets, and dangers. Adults often function as advocates for their children in order to make sure that school, community, and health care professionals provide needed resources.

The Years When Children Are Adolescents. Parents tend to view the years of their children's adolescence as extremely trying. In a national survey, over half of parents of adolescents say they worry that their children will struggle with anxiety or depression. Many worry that their children will have problems with drugs or alcohol, or with unwanted pregnancy. Especially among those with family incomes under $30,000, parents of adolescents worry that their children might get beat up, shot, or be in trouble with the law. These worries are linked to their view that their neighborhood is not a very good place to raise kids (Pew Research Center, 2015).

Adolescents are likely to seek new levels of behavioral independence. They spend most of the day away from home and apart from adult supervision. As adolescents gain in physical stature and cognitive skills, they are likely to challenge parental authority. During this time, the principles that parents have emphasized as important for responsible, moral behavior are frequently tested. Children are exposed to many voices—including the media, popular heroes and heroines, peers, and school adults—that suggest there may be more than one ideal way to behave and more than one definition of success. Successful parents of adolescents attempt to balance autonomy granting (opportunities for their children to make their own decisions), responsiveness, warmth and support, communication about high standards, and limit setting in the needed proportions so that their children can grow increasingly independent while still being able to rely on an atmosphere of family guidance and reassurance (Steinberg, 2001).

Adolescent children are the front line of each new generation. The questions they raise and the choices they make reflect not only what they have learned, but also what they are experiencing in the present and what they anticipate in the future. Parents of adolescents are likely to feel persistent pressure to reevaluate their own socialization and their effectiveness as parents. Questions are raised about their preparation for their own future as well as their children's. The ego boost parents experienced from being viewed as wise and resourceful when their children were young is likely to be replaced by doubt as they and their children face an uncertain future. Parents who can respond to their adolescents in an open, supportive way can benefit by finding opportunities to clarify their own values. They can begin building new parent–child relationships that will carry them and their emerging adult children into later adulthood.

The Years When Children Are Adults. When children make their own transitions into adulthood results in new patterns of interaction between parents and children and new opportunities

Courtesy of Philip Newman

The demands of parenting change as children move through different stages of development. In early and middle childhood parents lead the way in guiding their children on new experiences and adventures. In adolescence, parents often try to support their children's emerging interests and goals.

for the middle adult parents. Alternative patterns are clearly evident as children take a variety of paths toward self-sufficiency and entry into adult roles. In general, adult children and their middle adult parents are more involved in each other's lives and in closer contact today than they were 30 years ago. There is some speculation that middle adult parents, having grown up in an era when parents and children were more distant, have made a more deliberate effort to create a family environment of interdependence and open communication. Adult children and their parents interact often on the phone, texts, through email, or face-to-face interactions. Middle adult parents provide frequent financial, emotional, and practical support, and children typically view their parents' support as contributing in important ways to their quality of life (Fingerman, Cheng, Tighe, Birditt, & Zarit, 2012).

Family roles change during this time. Most women enter menopause bringing a close to the couple's natural childbearing years. The relationship between the parents also changes as parenting activities diminish. Some couples become closer—closer than they have been since they first fell in love. However, divorces also occur after the children leave home. Parents begin a review and evaluation of their performance as parents as they see the kinds of lives their children have established for themselves. Erikson (Erikson et al., 1986) found that during this period, many parents continue to build their identities on the accomplishments of their children.

The period when children leave home does not seem to be a negative time for adults. A woman who was anticipating her children leaving home described her feelings this way:

> From the day the kids are born, if it's not one thing, it's another. After all these years of being responsible for them, you finally get to the point where you want to scream, "Fall out of the nest already, you guys, will you? It's time." It's as if I want to take myself back after all these years—to give me back to me, if you know what I mean. Of course, that's providing there's any "me" left. (Rubin, 1980, p. 313)

Parents are usually pleased as they follow their children's accomplishments. According to a national survey of parents whose children were ages 18 to 29, 73 percent responded that they had mostly positive relationships with their children, and 86 percent named their children as a source of enjoyment (*U.S.A. Today*, 2013). Of course, adults maintain certain parental functions during this stage. Many children remain fully or partly financially dependent on their parents during their 20s and 30s. If the children are in college or in postgraduate study, their parents may experience greater financial demands than at any earlier period in their parenting history. In many families, parents take on additional jobs and loans to meet the financial requirements of their children's education. Adult children may turn to their parents to provide financial resources in order to take advantage of new opportunities, like training or advanced degrees, or to provide a safety net when their own financial situation deteriorates.

Children who have left home may not have resolved decisions about occupation and marriage. Their parents may remain a source of advice and support as they go through periods of identity and intimacy formation and consolidation. Parents begin to feel the pressure of challenges to their value orientation as their children experiment with new roles and lifestyles. During this stage, parents may serve as sounding boards or as jousting partners in young people's attempts to conceptualize their own lifestyle.

As less time is taken up with direct parenting responsibilities, parents may alter their roles and redirect their energies. However, some parents experience resistance from their children, who expect their parents to remain the same as they themselves change and grow. Young adult children may return home for intervals when they look for a new job, find a new roommate, recover from a love relationship that has ended, return from military service, or drop out of college. Throughout these transitions, young adults look to their parents as a source of stability and to their home as a safe harbor while they try to establish their own life structure.

One of the major family events that may occur during this period is the child's decision to cohabit or marry. Along with this new relationship comes a connection to an entirely new network of relationships, the partner's family. In the United States, most parents have little influence on their child's decisions in this matter. They may find themselves associated through marriage or intimate partnership with a family kinship group that differs significantly from their own or with one that shares many of their own family's beliefs and values.

The first few years of marriage can be somewhat precarious. Parents may have to reintegrate an adult child into the family at this stage if the marriage is not successful. An adult child who leaves a marriage may need some temporary parental reassurance and support in order to regain confidence in the ability to form an intimate relationship. Thus, at times of crisis, middle adults may need to practice parenting skills they have not used for a while and develop new skills in helping their children deal with new challenges.

Grandparenthood. Grandparenthood—the time when an adult witnesses the birth of a new generation—might be considered the beginning of an additional stage in family development. This transition to grandparenthood is outside one's own control. Whenever one's children have children of their own, the adult parent is propelled into a new ancestral role, and membership in an expanding kinship network. With grandparenthood, adults begin to observe their children as parents. Reflecting on their own roles 20 to 30 years earlier, they may attribute some of their children's successes to their own parenting techniques and may take responsibility for some of the failures (Erikson et al., 1986). In chapter 13 (Later Adulthood), we consider in greater detail the role of grandparenthood and its significance for adult development. Suffice it to say that as grandparents, adults have the opportunity to relate to small children as an expression of the continuity of their lives into the future. Of course, not all grandparents relate to their grandchildren from this philosophical point of view. However, the attainment of the grandparent role has the potential for bringing with it a new perspective on time, purpose, and the meaning of life that may serve as a source of reassurance during later adulthood.

Adults differ in how they define the role of grandparent. Most grandparents do not live with their grandchildren. The nature of their relationship and the quality of their influence depend largely on how often they interact. Grandparents may have the greatest

Grandparents and their grandchildren are having fun in a friendly board game. Everyone is a winner when they get to spend time together.

impact on their grandchildren indirectly in the way they support the child's adult parents, especially in times of crisis or distress, by providing emotional or instrumental support to the parents.

The better the relationship of grandparents to their adult children, the more likely it is that the grandparents and grandchildren will interact frequently and form a bond of affection and care (Dunifon, 2013). Grandparents may see themselves as carriers of the family traditions and dispensers of wisdom, as needed experts in child care, as convenient and trusted babysitters, or as admirers from afar. As grandparents, adults are asked to reinvest energy in small children. The quality of the relationship that develops between grandparents and their grandchildren depends not so much on the fact that they are relatives as on the kinds of experiences that the two generations share. Grandparents may also find that the quality of their relationship with their grandchildren is mediated by the child's parents. Especially when the grandchildren are little, the amount of time they spend with their grandparents and the way the grandparents view them are filtered through the quality of the adult relationship that their parents have with their own parents, the grandparents (Brubaker, 1990; Erber, 2013).

The process of expanding caring relationships through parenting can be stressful. It is full of conflicts and challenges, demanding time that the partners might otherwise spend with each other or in pursuit of their own interests and ambitions. However, parenting generates the kind of conflict that promises an enormous potential for personal growth. By providing a meaningful, responsive context for their children's lives, parents have the opportunity to articulate their own value systems and to observe the consequences of their efforts in the continuous development of their children. Psychosocial growth requires a willingness to engage in tasks that may temporarily increase stress, uncertainty, and complexity. Rather than turning away from or minimizing tension, development may require facing challenges that are difficult or intriguingly complex in hopes of growing while struggling to meet them.

Caring for One's Aging Parents

In addition to meeting the challenges of parenting, another test of one's capacity for generativity comes in the form of commitment to one's aging parents. One of the significant challenges of middle adulthood is the struggle to respond effectively to one's parents as well as to one's children and grandchildren. That is why middle adults are sometimes referred to as the *sandwich generation*, tucked in the middle between caring for one's children and caring for one's aging parents. This dual obligation may create new sources of role overload. As one ages from 30 to 50, one's parents may age from 60 to 80. With the advancing life expectancy, it is becoming increasingly likely that middle adults will be involved in meeting the needs of their own aging parents and grandparents. It is also increasingly probable that their aging parents will survive through a period of vigorous and independent later adulthood into a period of frail later life.

What Is Filial Obligation?

Filial obligation is a feeling of responsibility to care for one's parents. One way of thinking about filial obligation is that it is a sense of responsibility that adult children have to help their parents as they get old, especially when their physical or mental health declines. Another view is that filial obligation is a moral sense of duty that arises as one realizes and acknowledges the sacrifices one's parents have made and the sense of indebtedness for those sacrifices. This view is more compatible with the observation that a sense of filial obligation can be very salient in adolescence or early adulthood, not only in middle adulthood when one's parents are aging (Stein, 2009).

How do adult children define their responsibilities for their parents? One measure of filial obligation included five components: providing needed assistance, maintaining frequent contact, avoiding conflict, sharing appropriate personal information, and maintaining appropriate levels of self-sufficiency (Stein, 2009). Using this measure with a sample of middle adults whose parents were all living in assisted living communities, researchers found that the kind of help adults provided depended in part on their assessment of their parents' physical and mental health. The healthier the parents, the less sense of obligation the middle adults felt. When middle adults evaluated their parents' mental health as better than average but their physical health as worse, they were more inclined to provide more sharing of personal information. When they evaluated their parents' physical health as better than average but their mental health as worse, they were more inclined to provide assistance. Thus, the adults' sense of obligation was tailored to support their parents' strengths.

The expression of filial obligation is affected by one's culture as well as by the aging parent's well-being. A cross-national study of filial obligation compared responses from 1,200 adults in each of five countries: Norway, England, Germany, Spain, and Israel (Lowenstein & Daatland, 2006). Across all countries, most respondents acknowledged some level of filial obligation, although the extent of support was greater in Spain and Israel than in the northern European countries. The nature of the obligation was varied, more prescriptive in Spain and Israel, and more open to negotiation in the northern countries. Across countries, more help was given to older parents when they were unmarried and suffering from some kind of physical disability. Across countries, help was bidirectional, with aging adults providing emotional and financial support to their adult children as well as receiving support from them.

In fact, studies of intergenerational economic transfers find that, on average, adults 65 and older give more in cash and gifts than they receive from younger generations and that it is more likely that an adult child will live in the household of an older parent than the reverse (Fingerman, Miller, Birditt, & Zarit, 2009; Litwin, Vogel, Kunemund, & Kohli, 2008).

Who Provides Help? Family members play a key role in providing help to their aging parents. In a longitudinal study, mothers were asked about which of their children they expected to provide help if they became ill. Seven years later, they were interviewed again. It turned out that the child they expected to provide help was indeed more likely to be the one who did provide help as needed. Caregivers were more likely to share their mothers' values, to live close by, and to be daughters rather than sons (Pillemer & Suitor, 2014).

Daughters typically assume more responsibility for their aging parents than do sons—including care for their spouse's parents as well as their own (Allen, Blieszner, & Roberto, 2001). This involvement is one element of the basic kin-keeping tasks that have traditionally been incorporated into women's socialization. Daughters are more likely than sons to provide care for their aging parents even when the daughters are employed. However, several structural aspects of an adult child's employment may influence this gender difference (Sarkisian & Gerstel, 2004). Women typically earn less than men, and more men than women are self-employed. Both of these factors predict how much time an adult child will spend helping their aging parents. Adult children who earn lower wages are more likely to take time off to help their aging parent, and adults who are self-employed are less likely to take time off to help their aging parent. Thus, some of the gender difference in caregiving is interdependent with the nature of workplace commitments and demands.

In addition to the amount of time that adult children spend helping their parents, daughters also provide somewhat different kinds of help. Daughters provide more direct care, such as bathing or dressing a parent, as well as emotional support, such as listening to a parent's concerns or helping the parent feel important and loved. However, both sons and daughters are about equally likely to assist in some of the tasks involving relations with health and human service organizations, scheduling medical checkups, and reviewing insurance and other financial matters. Research shows that aging adults who have three or more children—whether they are sons or daughters—are more likely to end up living with one of them than are adults with fewer than three children. However, for other forms of support, such as receiving telephone calls, visiting, and help in daily tasks, older adults who have one daughter receive more support than those who have only sons (Spitze & Logan, 1990).

Although adult children provide much of the family support to aging parents, young adult grandchildren also report a sense of filial obligation and participate in the caregiving role (Fruhauf, Jarrott, & Allen, 2006). In a qualitative study of 17 grandchildren ages 21 to 29 who were actively involved in their grandparents' care, some began to take a more active role when another family member was no longer able to help. Eleven said that they respected and valued the time their grandparents spent with them as children, and this was a way for them to reciprocate.

Robyn derives a great deal of satisfaction from taking a walk with her mother. Because of physical frailty, her mother lives with her now. Robyn thinks about all the things her mother has done for her and all the sacrifices she made so that Robyn could go to college and have the life she now has. Robyn is very happy to take care of her mother and to still have her mother's company and wisdom.

Josh, who has been caring for his paternal grandparents since he started driving, voiced the sentiment of several grandchildren when he stated, "It just felt like it was what I was supposed to do. They helped me out . . . helped raise me and so now they need us. . . . Now it is time to give back" (Fruhauf et al., 2006, p. 899).

What Factors Promote an Optimal Relationship Between Adults and Their Aging Parents? The nature of the continuing relationship between adult children and their aging parents is not focused solely on caregiving. The norms of independence and self-sufficiency are strong among the current aging population, many of whom state that they do not need assistance from their adult children. However, when asked whom they view as their preferred source of assistance should they need it, aging parents mention their children first, before their friends, siblings, or other relatives. Likewise, adult children view themselves as being primarily responsible for meeting their parents' needs; however, most do not expect to have to meet a variety of such needs (Zarit & Eggebeen, 2002).

In adulthood, preserving and building a positive parent–child relationship is a dyadic process in which both middle adults and aging parents may need to gather new information and change old behaviors (AgriLife Extension, 2010; Lyons, Zarit, Sayer, & Whitlach, 2002). Thinking back to later adolescence and early adulthood, children may feel a sense of obligation to their parents, but they may not be in a position to reciprocate for the many ways their parents have helped them. During those stages of life, they continue to be dependent on their parents for emotional and instrumental support. However, sometime during early and middle adulthood, a socioemotional transition occurs. Middle adult children are likely to have achieved a greater sense of independence from their parents and to have the experience and resources needed to assist them in some valued ways.

However, the relationship of adults and their aging parents has a history. For some, this history is one of a positive attachment, mutual positive regard, and experiences in which parents skillfully balanced autonomy granting and closeness to create a family environment in which the children could emerge with the resources needed to form a strong personal identity. In other families in which children feel they were rejected or undermined by their parents, they emerge into adulthood with strong feelings of resentment or rebellion toward their parents. Their relationships with their parents are never close, and as they go off on their own, interactions become increasingly infrequent. These antecedents influence the nature and quality of filial obligation. Adult children and aging parents may find that they have predictable areas of conflict. They may not always share the same goals regarding care. In one qualitative study, researchers focused on how the parents and their adult daughters navigated situations when their goals about care differed. Daughters typically tried to reason with their mothers, expressing their concerns for their mothers' safety and health. Aging parents often ignored their daughters' requests. When goals differed, aging parents were described as "insisting, resisting, and persisting" suggesting that the path toward negotiated agreement was much more difficult. When goals were similar, the dyads seemed to find that their suggestions were respected and things went along well (Heid, Zerit, & Van Haitsma, 2016). Adult children who are providing care are likely to see this kind of resistance as a form of "stubbornness." Of course, some older adults just have a more disagreeable personality; they are stubborn by nature. What is more, the more severe their disability, the more their resistance is viewed by their children as stubbornness (Heid, Zarit, & Fingerman, 2015).

In a desire to reduce conflict, adults and aging parents may need to improve their approach to communication, or redefine problems so they do not continue to disrupt a caring relationship. Similarly, adult children and aging parents need to identify the activities they enjoy together and talk openly about how much time they want to spend together. For some parent–child bonds, a few hours a week or a weekend visit every so often may be all that is desired; for others, daily contact may be pleasant and satisfying. Adult children need to learn more about the changes associated with aging and begin to identify specific aspects of their parents' mental or physical health that may be impacted by aging. Aging parents need to learn more about the demands and stressors their children are facing in order to appreciate the constraints these demands place on their child's helping behaviors.

Adult children are sometimes in a position of trying to supplement the care and support they provide their parents by coordinating social services and interacting with various public agencies. Many feel unprepared for this aspect of the caring relationship (Zarit & Eggebeen, 2002). They are not comfortable dealing with hospitals, insurance agencies, social service agencies, or residential treatment facilities. However, when older adults require the services of these organizations, their adult children typically know their parents' unique needs and are among the best people to interpret them for service providers. Through such contacts, middle adults have the opportunity to modify and improve the services offered by these agencies, making them more effective for future generations of aging adults.

Research on caregiving within the family has begun to examine the rewards as well as the costs in this relationship (Robertson, Zarit, Duncan, Rovine, & Femia, 2007). Although quite a bit of attention has been given to caregiver strain, caregivers experience both positive and negative aspects of this role. The costs may include feelings of exhaustion, never having time for oneself, feeling overwhelmed by the demands of multiple roles, or experiencing the physical strain of caregiving. Rewards of the caregiving role may include feelings of being appreciated, putting life's demands into a new perspective, or feeling closer to the care recipient. In some cases, the care recipient is able to exchange resources with the caregiver, for example, by providing babysitting time for help with the grocery shopping.

In a study of the costs and rewards experienced by children and spouses who were caring for an aging parent or partner, adult children experienced more rewards in their caregiving role than did spouses, and women experienced more caregiving costs than did men. An unexpected finding was that for women, companionship from their spouse was an especially rewarding response from the care recipients (i.e., their husbands). Thus, the research underscores the reciprocal nature of caregiving, with rewards and costs flowing in both directions (Raschick & Ingersoll-Dayton, 2004). These ideas are reflected in the case study of a daughter caring for her ailing mother.

— CASE STUDY A Daughter Cares for Her Ailing Mother —

Lois Lyles reflects on what she learns from her mother as she provides care during her mother's last days of life.

Mama is down, I am up. Up, and up, and up. She wants Vaseline for her char-dry lips, her St. Francis church bulletin, her rosary. The vase on the dresser must be moved out of the way of the black-faced digital clock. Two twenty-five, New Year's afternoon. She stares at the red numerals each like an imp or an infernal flame, as the five becomes a six; the six, a seven. "Water the plants, Lois."

Nervously, I dribble water into the flower pots. I work fast. She has approximately one request every three minutes.

"Thank you, darling. I feel so worthless and useless. Why can't I do anything?"

"Mama, you are not worthless. You are a beautiful person. You still look beautiful to me," I say, and mean it. She was my childhood idol. Her soulful-eyed, smooth-haired beauty was my first acquaintance with romance.

"No, I'm not," she whimpers; then says, "Thank you, darling."

"Mama, whatever happens, I'm with you, and I'm for you." She cries. Her misery makes me recall how my fear of death had once made me, to my mortal shame, abandon a sick woman I loved. I am the namesake of Mama's sister Florence, who died of cancer four summers ago. Florence is my middle name. Mama must be thinking of Aunt Flo, too, for she says, "I took care of Sister when she went up to her bedroom three days before she died and never came downstairs again. I remember she was amazed that I would wash her down there, you know, her private parts. She didn't want me to have to do that." After pausing, my mother adds, "I thought, Lois, it would help you after this is over, to be with me now when I need you, and do things for me."

I am astonished at her, the good mother. She has called me to her sickbed, not so much as to help her as to help *me*. I, in childhood, was never hungry, never homeless, never seriously ill; and was never exposed to the sight of physical suffering. My parents had made sure of all that. But an easy ride of a life is only a half-truth. Now, Mama's gift is to let me know her pain. She is letting me see if I am strong enough to grapple, by proxy, with Death. (Lyles, 1991, p. 242)

CASE ANALYSIS Using What You Know

1. Explain the concept of filial obligation and how it is illustrated in this case.
2. List the costs of and rewards of caregiving in this case.
3. Based on the evidence, infer the quality of the mother–daughter relationship in this case.
4. Hypothesize how caring for her dying mother may influence Lois's development as an adult.

FURTHER REFLECTION: *Summarize the changing nature of the relationship of adults and their children as the children mature from middle childhood into early adulthood. Hypothesize how these changes may stimulate new psychosocial development for parents during their middle adulthood.*

Explain the concept of filial obligation. What have you observed about your parents and their relationship to their aging parents? What are your assumptions about how you will meet the needs of your parents as they age?

Consider the role of culture in shaping expectations about the relationship of adults and their aging parents. How do various ethnic practices and religious beliefs influence the way adults view their obligations to their parents?

Managing the Household

OBJECTIVE 4 Summarize the tasks required for effective management of the household and explain why they are necessary. Describe the diversity of households, including blended families, single-parent families, and adults who live alone, and hypothesize about the implications of these various household structures for individual development.

Household is a term that describes an entity that is created by people for a particular style of living. The household is a physical setting and a shared psychological context for a group of people. Households are bounded units of people who pool their resources, earn and spend money, interact with the labor market, and engage in social interaction with their neighbors (Wallerstein & Smith, 1991). The demands and tasks of household management stimulate cognitive, social, and personal development during adulthood.

The household provides a basic life structure for people in all cultures. The Hindu joint family illustrates the way that household management is culturally constructed, based on norms for gender, age, and kinship ties. In the traditional form of the joint family, parents, their children, and eventually their sons and the sons' wives and children live together. When daughters marry, they go to live with their husbands' families. Respect for age creates a dominance hierarchy. The eldest male is considered the head of the whole family, with the eldest son holding a position of dominance over other men in the family. The eldest is the head of the household. When a woman becomes a mother-in-law, her status increases. She supervises her daughters-in-law who are expected to make and serve the meals, wash the dishes, and keep the house clean. When daughters-in-law give birth to sons, their status increases. The dominance hierarchy, related roles, and approach to family decision-making are internalized as children grow up in this family and observe the relationships among parents and their children, husbands and their wives (Valsiner, 2000; Gardiner & Kosmitzki, 2011).

Management of the household refers to all the planning, problem solving, and activities adults undertake in order to take care of themselves and others who are entrusted to their care. At present, society's ability to recognize and value the accomplishments linked to the management of the household is poorly developed. At the same time, more emphasis is being placed on the centrality of the home environment in fostering intellectual development, social competence, health, and emotional well-being.

The household is a system. The stability and predictability of life for members of the household is supported by the shared understanding of roles and rules. The roles refer to expectations about how each person in the household is expected to behave; rules refer to explicit or implicit norms about such matters as the quality of interactions, decision-making, and use of resources (Palkovitz, Trask, & Adamsons, 2014). The household system has the potential for providing an environment that facilitates human growth and mental health. Learning to create such an environment is a developmental task of the middle adult years. Households have the potential for much greater variety and flexibility than most work settings. However, many of the tasks required for household maintenance are tedious, physically demanding, repetitious, and time consuming. As women have become more intensively involved in the labor market, research has focused on how much time people spend at the tasks of household maintenance and who is performing those tasks.

Managing Resources and Meeting Needs

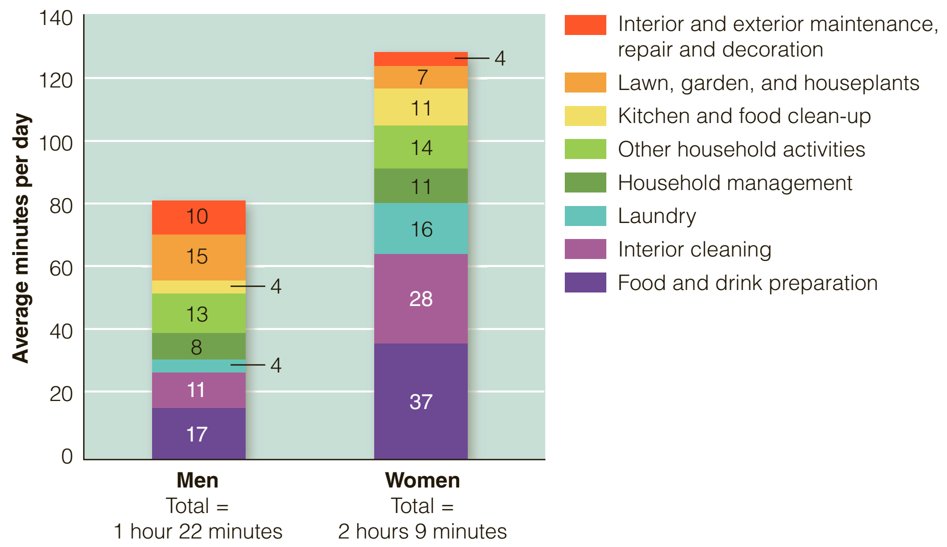
Data gathered through daily time diaries provide a picture of the amount of time devoted to various household tasks and the involvement of men and women in those tasks in the United States (Bureau of Labor Statistics, 2015). These data help clarify the diversity of household tasks, the amount of time devoted to those tasks, and the way the division of labor between men and women is played out in the management of the household. FIGURE 12.2 ▶ shows the average number of hours spent in each activity per day by men and women. With the exception of lawn and garden care, and indoor and outdoor maintenance, women spend more time than men in each of these household activities. In comparison to patterns of time use from the 1960s, fewer hours are devoted to household tasks overall, and more time is devoted to child care by both men and women. Dual-career couples are more likely to purchase services for household tasks and are especially likely to order in meals or to eat out as a way of saving time (Casper & Bianchi, 2002).

The challenge of household management is to create an environment that supports both individual and group functioning. The significance of the household can be appreciated by thinking about the consequences of its absence, especially in the case of homeless individuals and families (see the **Applying Theory and Research** box Homelessness), or in crises such as hurricanes, fires, or floods when people are displaced from their homes. Management of the household, much like the workplace, requires leadership in order to set priorities and goals, manage resources, and operationalize plans. The scarcer the resources, the greater the pressure on the adult to make careful decisions and to find creative solutions to the daily challenges of meeting the household's physical and psychological needs. Leadership begins as adults model the process of shared decision making and children (if there are any) learn to participate in problem solving. Household members discover ways to work together to achieve a shared vision of the future. The home environment is the first place where many children discover that they can have a voice. Parents can create a family atmosphere in which the spirit of democracy comes alive through a careful balance of freedom and responsibility, respect for individuality, and commitment to the welfare of others.

Building Networks and Coalitions

One of the most difficult and subtle kinds of new learning that occurs during middle adulthood is the development of an understanding of how the structures of other organizations affect one's life and the lives of family members. These other organizations may include (1) members of the **extended family** (e.g., one's in-laws), (2) other families, (3) business or work-related associations, (4) religious groups, (5) educational groups, and (6) community groups. The family is interconnected with other social systems that can expand its resources. Its contact with social groups must include the maintenance of goodwill and some evidence of group identification and commitment. Social groups also generate norms that may make demands on the family. Hence, adults must be able to protect the family from excessive external demands, while retaining valuable and satisfying external relationships.

Families differ in their investment in relationships outside the family unit. In some households, the nuclear family is more



Note: Data include all noninstitutional persons age 15 and over. Data includes all days of the week and are annual averages for 2014. Travel related to these activities is not included in these estimates.

APPLYING THEORY AND RESEARCH TO LIFE

Homelessness

The term homeless refers to people who have no permanent resting place and no private space (Nunez, 2004). Although many estimates focus on individuals who are living on the streets, in emergency shelters, or in transitional housing, there are also individuals who are living with friends or relatives, moving from one location to the next every few weeks. It is difficult to assess the exact number of people who experience homelessness; the numbers often reflect a specific point in time rather than a lifetime estimate. The National Alliance to End Homelessness reported a point-in-time estimate of 564,708 people experiencing homelessness in January 2015, a decrease of 2 percent since 2014. Whereas 33 states and DC reported decreases in homelessness from 2014 to 2015, 16 states reported increases (National Alliance to End Homelessness, 2016). This count did not include people who were in shelters for abused women, people who were living in outdoor areas typically inhabited by the homeless, people who may have avoided the shelter on that day in order to prevent being counted, and people who were housed in some other form of temporary housing with family and friends.

In some locations, many people who seek shelter cannot be accommodated. A survey by the U.S. Conference of Mayors (2014) reported that of 25 cities surveyed, "because no beds were available, emergency shelters in 73 percent of the survey cities had to turn away homeless families with children. Shelters in 61 percent of the cities had to turn away unaccompanied individuals." Thus, efforts to count the homeless, even on a specific day, are likely to be inaccurate.

The majority of the homeless population, roughly 63 percent, are individuals, and 37 percent are families. A survey of 25 U.S. cities found that children comprise about one third of all homeless people (U.S. Conference of Mayors, 2014). The proportion of families with children who are homeless is estimated to be higher in rural areas.

A combination of three major factors contributes to the continued risk of homelessness for families with children in the United States: (1) the decline in the value of the minimum wage, coupled with the prevalence of insecure jobs with few or no benefits; (2) the decline in the availability and value of social welfare benefits; and (3) shortages in low-income housing and public-assistance housing (National Coalition for the Homeless, 2014). Many adults are described as "rent poor," meaning that they are using 50 percent or more of their income for housing.

Paths toward homelessness for families are diverse. Some of the most common precursors are job loss, domestic violence, substance abuse, mental illness, and divorce. Although some homeless individuals are in a sudden crisis, many have stumbled from one temporary living situation to the next, and others have never been able to establish a permanent home. Some of these people are singularly alone and unable to develop minimal social relationships. This is an unusual phenomenon because most people have some ability to have meaningful social ties. Among homeless mothers, for example, many have friends or family but cannot count on them for housing support. For some, the nature of their housing crisis may disrupt their social network, making it impossible to ask for help from family or friends. Following an episode of homelessness, some families are relocated far from their social network, making it likely that they will become vulnerable to homelessness in the future (Toohey, Shinn, & Weitzman, 2004). As a result of victimization earlier in their lives, some women suffer from a degree of emotional dysfunction, exacerbated by the use of alcohol and drugs. An estimated 10 percent to 15 percent of homeless parents have a problem with drug addiction, making it difficult for them to hold a job, sustain a relationship, or be approved for low-cost housing (Nunez, 2004).

In homelessness, society exhibits a painful example of psychosocial stagnation—the inability of mature adults to meet their (and their children's) basic needs for shelter, food, and clothing—combined with its own failure to prevent this degree of vulnerability. In the face of the cultural value placed on independence, self-sufficiency, and hard work, U.S. society has difficulty making effective public responses. In fact, national policies have operated to increase

Louise earns a bit of money by redeeming aluminum cans and bottles. She lives in a temporary shelter in Battery Park, and walks daily in full view of the Statue of Liberty.

homelessness and the stressors of living on the streets. Since 1975, there has been a steady decrease in federal funding for low-income rural and urban housing accompanied by the loss of low-cost units that qualify for public assistance. There was a temporary increase in funding from 2009 to 2012 with the Homeless Prevention and Rapid Rehousing program, which was part of the American Recovery and Reinvestment Act of 2009, but the program ended in 2012. Recent across-the-board budget cuts have further compromised funds for public housing.

Over this time, a growing number of cities have enacted laws that criminalize homelessness, making it illegal to sleep, camp, eat, beg, or store personal belongings in public places. The police make periodic sweeps of areas known as gathering places for the homeless, forcing them to leave their personal belongings and to move to outlying areas.

Critical Thinking Questions

1. What are you assumptions about the causes of homelessness? How does the evidence support your assumptions?
2. Describe how the experiences of homelessness may interfere with psychosocial development in adulthood.
3. Summarize the physical, psychological, and social needs of people who are homeless. As a student of human development, what two suggestions would you give to policy makers regarding reducing homelessness in the United States?
4. Look up the approach to homelessness in one of the following major cities: Los Angeles, New York, Boston, Atlanta, and Miami. What are the primary strategies being implemented in this city? Who is responsible for the success of these programs? How are they funded? How do these programs address basic themes of human development in middle adulthood?
5. Roughly 10 percent of the homeless are veterans. Investigate the conditions that are associated with homelessness for veterans.

important than any other group. Such households expend little energy outside the family boundaries. At the other extreme are families who are involved in a number of community groups and who incorporate their extended families into frequent group activities. In some families, each person is encouraged to establish a group of close friends. In others, each person's friends are screened or evaluated by the other family members. The adult's task is to define the family's preferred stance toward other individuals and social groups and to create opportunities to build desired relationships.

Friendships are known to contribute to well-being in adulthood. However, among people in middle adulthood one observes different patterns in the approach to friendship. Some people are very selective, preserving a small number of close friends who have been in their network over a long time and with whom they experience frequent interactions and emotional closeness. Others prefer to keep their distance, having relatively few contacts with friends. Still others acquire new friends throughout their adulthood. Circumstances can solidify or disrupt these friendship networks. For example, some people continue to live in the same community where they went to high school; they maintain ties with these friends well into midlife. Adults whose children attended school together may continue to be friends as their children grow up. For others, experiences of job loss, divorce, illness, or moving to a new community may disrupt friendship networks (Miche, Huxhold, & Stevens, 2013).

Preserving relationships within the extended family is a delicate matter. This is the realm of family politics. In close family relations, it is likely that positive feelings of warmth and affection are coupled with negative feelings of irritation and aggravation (Fingerman, Hay, & Birditt, 2004). Failed expectations about courtesies and obligations or thoughtless insults and slights from family members are typical stressors that occur within the family network. Family members may have opposing political, religious, or childrearing views; they may have competing motivations; or they may try to form alliances among family subgroups. When children decide to marry, they bring two family networks together that may or may not get along. Parents may or may not convey support to their child's partner or spouse; sisters and brothers have partners who may or may not support each other. Likewise, parents may divorce and remarry, bringing one family system into contact with another. All these transitions introduce challenges to sustaining valued coalitions within the extended family and protecting the family from disruptive forces.

Much of this chapter has focused on two-adult families, especially those with children, often in the dual-earner arrangement. In the following sections, three alternative forms of households are described: remarriage and **blended families**, one-parent families, and single-person households, each of which poses unique opportunities and challenges for household management.

Remarriage and Blended families

According to a national survey of marriages and divorce in the United States in 2013, by the age of 50 to 59, roughly 20 percent of men and women had been married twice and 6 percent had been married three or more times (Kreider & Ellis, 2011; Livingston, 2014). The psychosocial reality of **remarriage** is unique for each family. Partners come to the remarriage with different marital histories. One or both have a former spouse and in-laws from a previous marriage.

In some cases, the relationships with the former spouse or the in-laws may involve unresolved conflicts. In other cases, relationships with the former spouse or in-laws from a previous marriage may continue to be close. If either partner has children, the remarriage involves a family formation between the adult partners, and the establishment of new parental roles and the negotiation of ties with noncustodial parents and grandparents. Custody arrangements may require that the parents remain in the same state or community in order to facilitate visitation. As a result, the remarried couple's life choices are constrained. The complexities of considering these extended family bonds can become difficult as the new, blended family approaches traditional holidays, celebrations, and transitions (Portrie & Hill, 2005).

One of the significant sources of ambiguity in a blended family is the relationship of stepparents to their nonbiological stepchildren. Although the most typical character in fairytales and myths about blended families is the stepmother, in fact the most common blended family is one in which a man marries a woman who has custody of her children, thereby entering into the role of stepfather. What determines whether a man will embrace this role, investing in another man's children as his own? William Marsiglio (2004) has provided a glimpse into the complexity of this process as men approach the social, personal, and interpersonal nature of becoming invested in their stepfather role. For some men, like Monty, the role is continuously ambiguous:

> I never really understood what I was to her; I still don't. I felt, I've always felt, like I should have been her father, but I never was, and I never will be. . . . I was always there for her, in positive ways, and he never was; I mean, never. (Marsiglio, 2004, p. 28)

For others, like Terry, there is an openness to the possibility of sharing the role with the biological father:

> Look, it's OK to have two dads. You have a couple sets of grandparents and whatever. It's OK to have two different fathers. I'm the one that's here with you all the time and he's the one up there. If he gets more involved in your life, then great! If he doesn't, nothing changes. I'm still here. I'm the one that's going to be here every day. (Marsiglio, 2004, p. 30)

For still others, like Doug, there is no room for ambiguity:

> I told her, I'll marry you, but that's my son legally. No step involved, nothing like that. That's my son. She said, "Fine; I don't see anything wrong with that." So that's when she went back to him [biological father] and said she don't want any alimony, child support, nothing. Just want you out of the picture. He signed the papers; he said, "No problem. I won't cause any trouble." So when the papers came back, they just simply read my name, didn't say stepfather or nothing else. (Marsiglio, 2004, p. 33)

The American Psychological Association (2016) identified three key issues that couples want to address as they consider remarriage and the formation of a blended family:

Michael Newman/Photo Edit

In this blended family, Tony is Berta's stepfather and Andrew's biological father. The children mean everything to Tony, and they both adore him.

1. Living arrangements and financial issues. These two concerns involve making plans for where the new family is going to live, particularly the desirability of creating a new home for the new family, and how to coordinate and share financial resources so that the partners have a sense of shared financial decision-making.
2. Addressing and resolving dynamics associated with the former partner/parent. This is especially important when former spouses continue to have relationships with children in the newly formed family.
3. Anticipating and communicating about new parenting roles, especially how the new spouse will interact with and form a meaningful role in the care, supervision, guidance, and discipline of their partner's children.

In remarriage, partners must find ways to create boundaries around the blended family so that children can benefit from the love and support of their parents, grandparents, and other relatives, while protecting the new family from unwanted intrusions and pressures for competing loyalties. Blended families have to find new traditions and rituals to mark their distinctiveness while preserving links to valued relationships from the past.

One-Parent Families

In 2012, about 27 percent of all families with children under the age of 18 were one-parent families: 77 percent were headed by women, 23 percent by men (Vesp, Lewis & Kreider, 2013). This compares to 22 percent of all U.S. families in 1980.

The greatest stressor for single mothers is the lack of financial resources. Roughly 38 percent of families with single-mother households and children under the age of 18 had family incomes less than 100 percent of the poverty level in 2012 (Vespa, Lewis, & Kreider, 2013). To put this figure in context, 9 percent of children in families with two married parents had family incomes at 100 percent of the poverty level or less. Thus, children in single-mother families are over four times more likely to live in poverty than children in two-parent families. Poverty in these families is the result of a number of factors: Single mothers tend to have a lower earning capacity, they work fewer hours, and even when they receive some support from the child's father, they bear a substantial portion of their children's expenses.

In addition to stresses associated with poverty, single parents may suffer from social isolation, continuous pressure to meet the needs of their children, and overload in trying to combine work, parenting, and household decision making without a partner. How well can single mothers manage their parenting role in the face of their many role demands? Some studies emphasize a deficit perspective—for example, identifying factors that place children or adolescents from single-parent families at risk for antisocial behavior and delinquency. Other studies focus on adaptation and coping within the single-parent structure. They consider factors that help sustain a positive parent–child relationship, such as sharing a strong emotional connection with other family members, being able to help one another in concrete ways, talking with one another and listening, and spending time together as parent–child and with other family members (McCreary & Dancy, 2004; Simons, Beaman, Conger, & Chao, 1993).

Reggie Casagrande/Jupiterimages

Jolene is very pleased to be able to spend time with her daughter Karen and granddaughter Margaret. As a single mom, she knows how important it is for Karen to have someone to help her and to spend time with her. When Ray walked out, Karen was devastated financially and depressed emotionally. Jolene helped Karen get a lawyer who was able to get Ray to fulfill his obligation to provide child support. She also babysat with Margaret while Karen pursued her MFA. With the new degree, Karen was able to get a good job and to regain her joie de vivre.

Retrospective studies show that many children who are identified as having psychological problems, especially temper tantrums, being a bully, cheating, stealing, and fighting, are from divorced, single-mother families. However, prospective studies—those that look at childrearing practices and subsequent child outcomes—show that poor parenting practices, especially emotional unavailability, ineffective discipline, minimal supervision, and a dominating, hostile style of interaction, produce these negative child outcomes in both single-parent and two-parent families. Family instability, especially the loss of parental figures and frequent changes in adults in the household, are more predictive of negative cognitive and health outcomes for children than the single-parent structure itself (Waldfogel, Craigie, & Brooks-Gunn, 2010). Although single-parent families face many additional problems, it is clearly inaccurate to label all of them as problem families.

Among single-mother families, one of the fastest growing subgroups is low-income women who have never been married (Casper & Bianchi, 2002). These women may be in cohabiting or serious romantic relationships, but for a variety of reasons they have rejected the idea of getting married. It is not that marriage is devalued; in fact, some argue that it is the high standards that these women have for marriage that makes them decide to stay single (Edin, Kefalas, & Reed, 2004). Women want to be able to find a partner whom they can trust to be faithful—someone who is not addicted to drugs or alcohol, who will treat them and their children with kindness, and who will be able to contribute financially to their family. In many communities, this type of partner is difficult to find. Rushing into a marriage with someone who does not have these qualities just because one has a child seems foolhardy. These women know of too many instances of couples who start out with great expectations and then run into job loss, infidelity, abuse, drunkenness, or criminal behavior. Thus, for many women, being an unmarried, single parent is a deliberate strategy for avoiding a difficult relationship and a potentially costly divorce (Edin & Kefalas, 2011).

People Who Live Alone

In 2012, about 32 million people in the United States lived alone. These one-person households were more likely to consist of men in the younger age groups (under 44) and women in the older age groups (45 and older) (Vespa, Lewis, & Kreider, 2013). Single-person households include people who have never married, are divorced or separated, and are widowed. The reasons for living alone and the backgrounds for this life pattern vary considerably.

Little is known about the differences in psychosocial development between adults who live alone and those who live with others. Some of the aspects of household management, including organizing time, planning for the future, making decisions, and establishing relationships with other social groups, pose challenges to the person living alone. On the other hand, assigning responsibility and establishing a pattern for group decision making are clearly not required. People who live alone may not feel the need to engage in elaborate planning and evaluation when they are the only ones who will be immediately affected by their choices. They may be freer to decide spontaneously as each opportunity presents itself. Living alone allows some freedom from adapting to the demands and needs of others, thus leaving time to focus on one's own preferences, projects, and interests. Some studies find that people who live alone are more likely to get out of the home, spend time with friends and neighbors, go to restaurants, and attend art classes and lectures than those in married or cohabiting relationships. These trends are not only observed in early adulthood, but also in middle and later adulthood. The freedom to initiate interactions and activities and the desire to remain socially connected may stimulate a more proactive approach to selecting and engaging in social life (Klinenberg, 2012).

FURTHER REFLECTION: *Describe the primary functions required for managing a household. Explain how the ability to perform these functions might contribute to the physical and mental health of the members of the household. How might failure to perform these functions undermine the physical and mental well-being of members of the household?*

Reflect on the way your parent(s) managed the household as you were growing up. How aware were you of their decision making and how much did you participate in the decisions that were made regarding household management?

How will your approach to household management differ from that of your parents? Explain the reasons behind these similarities and differences.

The Psychosocial Crisis: Generativity Versus Stagnation

OBJECTIVE 5 Define and explain the psychosocial crisis of generativity versus stagnation and the central processes through which the crisis is resolved: person–environment interaction and creativity, the primary adaptive ego strength of care, and the core pathology of rejectivity.

The psychosocial crisis of *generativity versus stagnation* can be understood as pressure to be committed to improving the life conditions of future generations (Erikson, 1963). Generativity is essential for both personal well-being and for the survival of any society. The maturing person experiences an increasing urgency to clarify the meaning and purpose of life beyond the satisfaction of immediate safety and security needs. To some degree, this motive is aroused as one recognizes the inevitability of mortality—that one will not be around forever to direct the course of events. Therefore, one must make contributions to the society, on both personal and public levels, that will stand some chance of continuing after one's death. At the same time, adult members of the society, who are typically in positions of authority and in control of resources, must begin to feel an obligation to contribute their resources, skills, and creativity to improving the quality of life for future generations in the hopes that the younger members of society will survive and thrive (de St. Aubin, McAdams, & Kim, 2004; Hofer et al., 2008).

There is an old story about three men who were observed laying bricks for the wall of a church. When asked what they were doing, the first man said he was laying bricks, the second said he was building a wall, and the third said he was building a church. As the story implies, during middle adulthood one must arrive at a philosophy of life that will impart significance to daily activities. One part of generativity lies in the actual attainment of creative goals. The other part lies in the perspective one brings to one's lifework, an outlook that appreciates the relationship of one's life and one's efforts to promoting well-being for the next generation. In contrast, stagnation reflects an outlook dedicated to preserving or embellishing one's power and resources without regard for the impact of this self-centeredness on the long-term well-being of the larger community.

Generativity

Generativity "encompasses procreativity, productivity, and creativity, and thus the generation of new beings, as well as of new products and new ideas, including a kind of self-generation concerned with further identity development" (Erikson, 1982, p. 67). Generativity is formed as a result of experiences of maintaining the world, nurturing and being concerned, and caring (Erikson et al., 1986).

It is worth pausing to consider what it means to *generate*. A basic dictionary definition is "to bring into existence." Through generativity, adults may change the world by introducing new things, ideas, beings, or bonds of relationship—all of which had not existed before. Although Erikson directed us to the heightened importance of generativity for development in middle adulthood, it makes sense to view this critical capacity as emerging over the life course. Stewart and Vandewater (1998) suggested that generativity arises through three phases: (1) generative desire or motivation, (2) a belief in one's capacity for generative action, and (3) a subjective sense of generative accomplishment.

The most obvious expression of generativity in middle adulthood is through parenting. Although not all parents are generative, those who are create a family environment that nurtures agreeable, conscientious children (Peterson, 2006). Adolescents whose parents have strong generative motives and who exhibit generative actions are likely to identify with these values and express generative concern in their own goals (Pratt, Norris, Hebblethwaite, & Arnold, 2008). This motive might be expressed in the formation of caring relationships with friends or siblings, as well as in the articulation of broader generative goals. For example, young people who want to promote better interracial understanding or to improve the educational experiences of young children might be said to have generative motives (Pratt, Arnold, & Lawford, 2009).

Studies have linked generativity to environmental practices. Parents who have strong generative motives are also likely to embrace environmental values and to socialize their children to enact environmentally conscious behaviors. As a result, the adolescent children also share their parents' environmental values and behaviors. Thus, generativity not only makes its impact on future generations through the care and concern of adults for their physical environment, but also through the passing on of these values to the next generation (Matsuba et al., 2012; Pratt, Norris, Alisat, & Bisson, 2013).

Parenting is by no means the only path to a sense of generativity. In a comparison of parents and childless adults, the link between generativity and psychological well-being was equally strong for both groups (Rothrauff & Cooney, 2008). Generativity may be expressed through a variety of actions, including procreation, parenting, invention, teaching, mentoring in the workplace, expanding the knowledge base, improving the physical or social environment, and artistic creation (Clark & Arnold, 2008; Kotre, 1995a). Generativity may be expressed by volunteering for a program like Big Brothers, Big Sisters; teaching skills or passing on knowledge to others; through innovations in the workplace; in the scientist's lab; in poetry, art, music, or literature; or in creating some splendid form of recreation, like a theme park or a refreshing new food like frozen yogurt.

Generative concern may involve recognition that there are problems or challenges facing the community that need to be addressed in order to ensure the well-being of the next generation. This awareness suggests a commitment to social involvement and community engagement. In a study designed to examine this relationship, generativity was assessed in a sample of African American and European American adults ages 34 to 65. Individual differences in generativity were associated with social support from family and friends, involvement in religious activities, and political participation. Those individuals who scored higher in measures of generativity were also more likely to emphasize pro-social values in raising their children and were especially conscious of the way they served as role models for their children. African Americans scored significantly higher on measures of generative concern and generative action than European Americans, suggesting a cultural context for the support and value of generativity within various ethnic communities (Hart, McAdams, Hirsch, & Bauer, 2001; Newton & Jones, 2016).

Courtesy of Philip Newman

A proud mentor and her outstanding graduate student celebrate commencement. The relationship of mentor and student expresses a form of generativity—a dedication to learning and discovery that is passed along from one generation to the next.

In looking back on one's life, one can assess one's actions and make a judgment about whether one's generative aspirations or motives have been realized. Erikson suggested that the outcome of the crisis of generativity versus stagnation has implications for adults at the next life stage in the form of *grand-generativity:*

> The reconciling of generativity and stagnation involves the elder in expressing a "grand-generativity" that is somehow beyond middle age's direct responsibility for maintaining the world. The roles of aging parent, grandparent, old friend, consultant, adviser, and mentor all provide the aging adult with essential social opportunities to experience grand-generativity in current relationships with people of all ages. In these relationships, the individual seeks to integrate outward-looking care for others with inward-looking concern for self. As a complement to caring for others, the elder is also challenged to accept from others that caring which is required, and to do so in a way that is itself caring. In the context of the generational cycle, it is incumbent upon the aged to enhance feelings of generativity in their caregivers from the younger generations. (Erikson et al., 1986, pp. 74–75)

Measuring Generativity

The meaning of generativity is being clarified through attempts to measure it (Hawkins & Dollahite, 1997; McAdams & de St. Aubin, 1998; Peterson & Stewart, 1993). In a cross- sectional comparison of dimensions of generativity among participants in early (22–27), middle (37–42), and later (67–72) adulthood, four aspects of generativity were measured (McAdams, de St. Aubin, & Logan, 1993):

- Generative concern—A sense that one is making a difference in the lives of others
- Generative commitment—Personal strivings or goals that have a generative nature
- Generative action—A checklist of actions that the person has performed in the past 2 months that involved creating, maintaining, or offering
- Generative narrative—Autobiographical recollections coded for generative meaning

Results suggest the following trends:

1. Across all age groups, generative concern was significantly correlated with happiness and life satisfaction.
2. When all four measures of generativity were combined, the middle adults scored higher than the young or older age groups.
3. The measures of generative commitment and generative narration were higher for the middle adult group.
4. The pattern of responses showed significant differences between the middle adult and the younger adult groups, but the middle adults and the older adults were not significantly different.

Once the generative orientation emerges, it appears to endure in the life goals and activities of a person into later adulthood (Villar, 2012).

Another approach to the measurement of generativity takes its inspiration from the construct of identity status that was introduced in chapter 10. In this view, generativity is defined as a commitment to "establish and guide the next generation through one's acts of care" (Bradley, 1997; Bradley & Marcia, 1998). Using a semi-structured interview, individuals are characterized along two dimensions: a person's level of involvement and active concern for the growth of the self and others, and a person's level of tolerance for differences in values, ideas, and traditions that reflects the inclusivity of their generative concern. Using these two dimensions, five types of generative status were described as fitting into one of five types:

- Generative: Vital involvement in growth for self and others and tolerance for a wide range of ideas
- Pseudogenerative-agentic: Active involvement in one's own growth and openness to a wide range of ideas for oneself, but not for others
- Pseudogenerative-communal: Active involvement to promote growth and tolerance for ideas in others, but not for oneself
- Conventional: Active involvement in growth for oneself and others, but low tolerance for different ideas and values
- Stagnant: Low involvement in growth for oneself and others and low tolerance for different ideas and values

This model expands the definition of generativity by making a distinction between people who are committed to growth for their own immediate circle and those who are committed to growth for humanity or a wider and more diverse population. It recognizes a group of middle adults who are generative toward those who are part of their in-group but not toward people whose ideas and values differ from their own.

— CASE STUDY My Leadership Journey: Health and Generative Action —

Lourie Campos describes how a leadership training experience transformed her generative strivings into action.

In the fall of 1999, I was encouraged to apply to the Women's Health Leadership program by my former boss. At that time, my job was a hodgepodge of responsibilities, although I was beginning to focus more and more on policy work. I felt that I lacked direction and the tools to make changes in my job. I didn't consider myself a "leader" even though my colleagues saw me as one. I wanted to be proactive in making positive changes in my job so I decided to apply to WHL. What I didn't expect was to learn as much about myself as I did about women's health issues.

In 1997, I was diagnosed with metastatic cancer. Years earlier, I saw my father lose his battle with colon cancer, which he courageously fought for 12 years, and in 1999 my brother was diagnosed with the same cancer. It has changed the way I think about my future. While work was important to me, I needed to set limits. While it may seem that participating in the WHL program would have added more stress to my life, it was just the opposite. Through WHL, I worked on an individual leadership development program that not only allowed me to be effective at my job by sharpening my skills and learning new ones but [also included] activities that I wanted to concentrate on outside of work. I spent more time having fun, learning new things, and spending quality time with my family and friends. WHL encourages personal and professional growth as well as teaching women to be advocates for themselves and other women in their community.

My major accomplishment was the creation of the *Women's Health Advocacy Guidebook*. The guidebook is specific to Santa Clara County and is full of information on the gaps and barriers low-income, medically underserved women face in Santa Clara County. It is a tool to help women's health advocates understand the legislative process and how they can participate in the process. I distributed 40 guidebooks to women in my community and I have had such a positive response from them. The guidebook is something I wish I had when I began doing policy work.

Prior to WHL, I had never spoken about my experience with cancer. I did not fully understand or recognize the positive impact my story could have. I was always afraid that if I spoke about my cancer and my family's experience with cancer people would just feel sorry for me, and that is the last thing I wanted. But WHL has taught me to take risks and to find my voice. This past year, I have been a featured speaker in a "Living with Cancer" series in Santa Cruz; I submitted my cancer story to the *San Jose Mercury News* and it was printed with a picture of me and my dog on the front page; I was a panelist on assembly member Elaine Alquist's "Women's Health Forum"; and I was selected as one of 8 people to represent California and to provide testimony to the President's Cancer Panel. Many people, especially women, have shared their experiences with me and I have felt so honored to listen to their stories.

CASE ANALYSIS Using What You Know

1. Describe the generative changes Lourie Campos experienced as a result of the Women's Health Leadership training experience.
2. Summarize how the case illustrates the following concepts: generative concern, generative commitment, generative action, generative narrative.

3. Explain the links between the developmental tasks of middle adulthood and the process of resolving the psychosocial crisis of generativity versus stagnation as they are evidenced in this case.
4. What role does the environment play in promoting generativity? Identify some examples of community programs or workplace initiatives that may foster psychosocial development in adulthood.
5. Speculate about possible causal links between a generative commitment in middle adulthood and health and longevity in later life. What evidence would you need to support this connection?

Stagnation

Stagnation suggests a lack of psychological movement or growth. Those unable to cope with managing a household, raising children, or managing their career are likely to feel psychological stagnation at the end of middle adulthood. Stagnation has been operationalized as an absence of investment in the growth of self or others and a rejection of ideas and values that differ from one's own. Stagnation is a distinct construct, not simply the absence of generativity. It is associated with the personality characteristic of neuroticism, indicating high levels of worry, and negatively associated with the personality characteristics of extraversion and openness to experience, indicating difficulties in social relationships, problems achieving a sense of social acceptance, and being highly controlled. Taken together, these characteristics suggest a person who is not only closed off to experiences with others but is also lacking in the kinds of experiences that would promote self-development (Van Hiel, Mervielde, & DeFruyt, 2006).

Narcissism

The experience of stagnation may differ for the narcissistic adult and the depressed adult. Thinking well of oneself, having a high opinion of one's abilities, and having more confidence in one's abilities than in the abilities and opinions of others, can be adaptive. However, in the extreme, narcissism is associated with "arrogance, feelings of superiority, a sense of entitlement, and lack of empathy for others" (Miller & Campbell, 2010). **Narcissistic people**—adults who devote their energy and skills to self-aggrandizement and personal satisfaction—are likely to have difficulty looking beyond their own needs or experiencing satisfaction in taking care of others. They are self-serving and defensive, expending energy to accumulate wealth and material possessions. They relate to others in terms of how people can serve them. Narcissistic people can exist quite happily until the physical and psychological consequences of aging begin to make an impact. At that point, and continuing toward elderhood, self-satisfaction is easily undermined by anxieties related to death. It is not uncommon for such people to undergo some form of religious or humanitarian "conversion" after a serious illness or an emotional crisis forces them to acknowledge the limitations of a totally self-involved lifestyle.

Depression

Chronically depressed people do not feel a sense of accomplishment during middle adulthood—they think of themselves as worthless. They are unable to perceive themselves as having sufficient resources to make any contribution to their society. They may have low self-esteem, doubt their opportunities for future improvement, and therefore become unwilling to invest energy in conceptualizing future progress. Adults who lack a belief in their own inner resources are vulnerable to chronic feelings of envy of others, which may be transformed into devaluation of others, and feelings of resentment or vengeance (Navaro & Schwartzberg, 2007). People who are chronically depressed and facing stagnation may lose their will to live. Their stagnation is tied to a loss of hope about the future and may increase the likelihood of suicidal thoughts and plans. The U.S. Centers for Disease Control and Prevention found that suicide among middle adults has risen steadily from 1999 to 2014, increasing by 43 percent for males and 63 percent for females in the age range 45 to 64 (Curtin, Warner, & Hedegaard, 2016). A combination of loss of financial resources, lack of control over one's life, feelings of being overwhelmed by stress, and loss of a sense of meaning and mattering may increase the level of stagnation to a point of giving up on life (Parker-Pope, 2013).

One source of stagnation in middle adulthood is **career stagnation**. Career stagnation can be a product of subjective factors at the personal or interpersonal levels or a product of objective conditions of the workplace. At the subjective level, people may be dissatisfied with their work; they may feel threatened by younger workers; they may be unable to attain valued work-related goals; or they may be stifled because of efforts to coordinate their career with that of their partner. Some people have been described as taking a "career maintenance" posture. They do everything possible to hold on to their position, even at the expense of undermining others or taking advantage of younger workers (Arnold & Clark, 2016).

At the objective level, people may be passed over for promotion, they may be a target of bullying, a victim of discrimination, or they may be fired or reassigned to a less desirable position (Abele, Volmer, & Spurk, 2012). Rather than taking up the challenge to mentor new employees, to invent new approaches to their work, or to seek another type of work, they become resentful, avoidant, and withdrawn. Career stagnation is likely to be associated with physical or emotional symptoms associated with the stress of work-related frustration (Clark & Arnold, 2008). The case of Lourie Campos illustrates how important the encouragement of professional development can be in forestalling stagnation and promoting continued generative growth in the workplace.

Middle adulthood extends over many years. During this stage, people encounter complex challenges for which they may not be fully prepared. Stressful life events are a certainty. Promotion to an administrative position, the need to care for an aging parent, and the negotiation of a divorce are examples. Both success and failure force people to redefine and reexamine their goals (Brim, 1992). At many points, adults doubt their ability to move ahead, achieve their goals, or make meaningful contributions. Feelings of stagnation surge temporarily.

The conditions that create uncertainty, struggle, and doubt are also times when new ego development is possible (Marcia, 2010). People may recognize that unless they redefine their situation or take some new risks, the quality of their lives will deteriorate. They face the possibility of feeling outdated by new technology, outmoded by new lifestyles, overburdened by role demands, or alienated from meaningful social contacts. At these moments of crisis, adults may become entangled in a process of self-protection and withdrawal that results in permanent stagnation. However, they may also be able to muster new resources and see things from a new perspective that will permit continuing growth and the expansion of generativity.

The Central Process: Person–Environment Interaction and Creativity

Two aspects of the central process that lead to the development of generativity in middle adulthood are **person–environment interaction** and **creativity**. The first refers to ongoing experiences between the individual and the social environment including family, work setting, neighborhood, and the larger political community. Day-to-day interactions, the expectations for behavior, the available resources, and the social supports that are necessary for the growth of self-confidence are elements of the social environment. The second part of the central process in the establishment of generativity is personal creativity. Although creativity has been defined in many ways, for our purposes we define it as the willingness to abandon old forms or patterns of doing things in favor of new ways. This requires the production, evaluation, and implementation of new ideas.

Person–Environment Interaction

Successful personality growth depends on the interaction between the demands of a person's immediate environment and one's own needs, skills, and interpersonal style. The concept of interaction suggests a potential for reciprocal influence between individuals and settings. People have an impact on the settings in which they participate. The structure and demands of settings may alter a person's behavior, values, goals, and sense of self-worth.

People have multiple identities and, as a result, participate in a variety of settings within their community. Person–environment interactions take place as employers modify work settings to enhance productivity, or as workers bargain through their unions to improve work benefits and conditions. Person–environment interactions take place as parents establish rules for family life, and as adolescent children react, resist, or redefine those rules. Person–environment interactions occur as community members protest police brutality and law enforcement officials respond with new training. Adults do more than maintain or respond to their environments; they shape them.

Adults with higher status—that is, more resources and power—are more able to influence the quality of interactions they have with others in their environment. In turn, they are more likely to create conditions in which they receive validation for their identities because they are treated with greater respect and recognition from others for the roles they play (Stets & Harrod, 2004).

In creating their environments, adults may decide whom they will marry, whether to have children, which occupation they will follow, and where they will live. To the degree that they have a choice in these matters, they are able to influence the kinds of transactions that occur between their personality and their social milieu. They build families with lifestyles that suit the members. Making good decisions about social settings requires that they understand themselves, the nature of other people, and the social institutions that are part of their social environment. The degree of fit between family needs and community characteristics helps support the essential functions of middle adulthood, including caring for children or aging parents, coordinating work and family life, and sustaining a vital marriage. When the community consists of other families facing similar tasks, the resources,

Some Chinese Americans choose to live and work in a Chinese ethnic community. They experience a sense of acceptance and support while contributing to the continuity of their cultural heritage.

mutual support, and validation for one's life choices are likely to be greater (Swisher, Sweet, & Moen, 2004).

Although participation in some settings is a matter of choice, many others are the result of chance. Some settings can be abandoned or altered if they do not meet the individual's needs; other settings are permanent and difficult to alter. If one is in an unsuitable setting, one must be willing to leave it if possible or discover a way to influence it so that it meets one's needs more adequately.

When one is forced to remain in social settings that are contrary to one's needs, the possibility of developing generativity is seriously diminished. If one is unable to experience a personal sense of effectiveness at home, at work, or in the community, then one is unlikely to feel capable of contributing to future growth in these spheres. Fortunately, the social environment is so multifaceted that individuals are likely to experience satisfaction in their participation in at least one setting, even if they are dissatisfied in others. For example, people are likely to experience a sense of validation in their relationships with friends and close family members even when they have difficulty experiencing recognition at work. This may require that individuals reorder their priorities. If there is little opportunity to find satisfaction in work, for example, one might begin to reinvest in contributions to one's family, religion, or community. Creativity is required in order to find a new balance among competing role demands while retaining a sense of joy and optimism.

Creativity

The importance of a creative response, no matter how small, is that it redefines the world and opens the door to new possibilities. Although the idea of creativity tends to be associated with the arts, we are using the term in a broader sense to suggest a novel transformation in any of a variety of domains from the practical to the theoretical—from creating a new recipe to creating a painting, a dance, or a theory of human behavior. Through creative effort, adults impose a new perspective on the organization, expression, or formulation of ideas.

Human evolution provides a rich history of the capacity for innovation. Archeological evidence stretching as far back as 3.4 million years shows remains of animal bones that were cut and marked for tool use. At some point, roughly 90,000 to 100,000 years ago, human creativity burst into a frenzy of innovation resulting in art, carvings, tools, hunting instruments, musical instruments, bowls, and bedding. Human capacities for symbolic representation, communication, and social interaction have combined to foster a rich production of new ideas. As humans come into contact with each other, they share information, pass on techniques, and build on one another's achievements to form a continuing thread of creative expression (Pringle, 2013).

Creativity is supported by aspects of brain function, personality, and experiences (Kaufman & Gregoire, 2016). At the neurological level, creativity is a product of the interplay among various large neural networks: executive attention, imagination, and the salience network. "Converging research findings do suggest that creative cognition recruits brain regions that are critical for daydreaming, imagining the future, remembering deeply personal memories, constructive internal reflection, meaning making, and social cognition" (Kaufman, 2013).

The neurotransmitter dopamine is responsible for the pleasurable experiences associated with exploration. The motivation to seek new experiences and to enjoy the stimulation associated with novelty is sustained in part by the release of dopamine. In addition to the motivating nature of dopamine release, creative individuals are thought to have a tendency to tune in to more details in their environment. They are less likely to screen out what others might consider redundant or irrelevant information. As a result, their minds are processing more information with the possible benefit of finding new connections among ideas or experiences that others have tuned out.

At the personality level, creativity is closely tied to the dimension of openness to experience. This can be expressed at the cognitive level in enjoyment of engaging with complex problems or ideas; at the emotional level in exploration of deep human emotions; and at the aesthetic level in the exploration of art, music, or natural beauty. People with this kind of open personality have a tendency to ask big questions, to look deeply into the meaning of their experiences, and to feel strong emotional reactions to sensory experiences. Finally, the combination of neurological factors that motivate exploration and personality factors that support openness to novelty contribute to an exploratory approach to life—engaging with new and novel experiences that open one's thinking and result in new ways to approach life's challenges (Kaufman & Gregoire, 2016).

Creative adults are not dominated by social forces but are able to direct the course of events themselves. They are at a point in their development at which their own creative responses can become a source of influence on others. Think about the menopausal woman who referred to her first hot flash as a *power surge*. Imagine the person who invented wheelchair basketball or the person who invented Post-Its. Consider the influence of parents who, by creating a flexible, open, and loosely structured home environment, nurture the self-expression of their children. In Columbus, Ohio, Dr. Alexander Bandar transformed an empty 65,000 square foot old shoe factory into the Columbus Idea Foundry, a makerspace where people learn to use old and new technologies and create their ideas. The Foundry is "stocked with woodworking machinery, metalworking equipment, welding rigs, CNC routers, laser cutters, 3D printers, glassworking facilities, photography studios and even an area for metal casting and blacksmithing. There's an area to learn coding, an Arduino room, a youth incubator, a leather stitchery, and equipment for making soap" (Noe, 2014). Through the process of creative problem solving, adults help reshape the social and physical environments in order to meet both personal and social needs.

Throughout middle adulthood, adults are faced with situations in family, childrearing, and work settings that provide stimuli for creative problem solving. In their efforts to take into account the requirements of the social setting and to be productive in it, people must develop creative plans. They must also attempt to carry out those plans—a task that may require further creativity. The essence of creative problem solving is to think outside the box—to resist defining the situation as it has been defined for you by others, then to formulate a new plan, and translate the plan into action.

The roots of creativity can be found in childhood, in the semiotic, representational, playful thinking of toddlerhood. As-if thinking—the ability to imagine a situation in some different configuration, to use objects to stand for something else, to give new names to familiar objects, to devise private symbols for common experiences, to take on imagined roles—all these capacities of symbolic play are the foundational building blocks of creativity. In our view, all humans are creative in the sense that they can pretend. All humans are creative when they cope effectively in a changing, unpredictable environment. All humans are creative in that they can invent games, songs, tools, artifacts, or messages that are new to them. It is not so important that the creative act is new to the world, but that it is new to the person who is inventing it (Sternberg, Grigorenko, & Singer, 2004).

From the outset, the creative process involves frustrations and risk. Typically, a creative solution is required because the standard way—the scripted way—is not working. In order to try new things, people must give up some old, reliable ways of thinking or behaving. In this process, people must anticipate the possibility that their efforts will fail. They may flounder for a seemingly long period, unable to identify the solution that will allow forward movement. They may worry about public embarrassment or humiliation. Given one's embeddedness in many demanding social roles, it is often difficult to step aside and view one's situation from a fresh perspective. For some, the anxiety and self-consciousness associated with prolonged uncertainty and possible failure may be so great that creative solutions are never realized. Their creativity is blocked by a fear of the unknown, or by an inability to violate conventional norms of behavior.

People who are hopeful about the future are more likely to overcome their reservations and doubts in order to press ahead with a creative plan. For those who are not inhibited by the fear of failure, the achievement of a creative solution is invigorating. For the great creative geniuses—such as Sigmund Freud, Albert Einstein, Isadora Duncan, or Pablo Picasso—a breakthrough or a profound creative insight fueled their commitment to pursue the creative path with increased energy (Gardner, 2011). Personal talent combined with an appreciation of the inadequacies of the current situation can lead to a significant creative act, which then promotes future efforts. Creativity provides an outlet for caring for something that has not yet been defined or experienced. Repeated efforts to generate creative solutions eventually result in the formulation of a transforming philosophy of life. Through risk taking, occasional failure, and a predominance of successful creative efforts, adults achieve a sense of what they believe in and what gives meaning to life. With this remarkable integration of experience and information, people enter later adulthood.

Creativity is expressed in many forms. The puppet maker surrounds himself with the creations of his imagination, inventing new characters and new ways of moving to entertain future generations.

The Prime Adaptive Ego Quality and the Core Pathology

Implied in the concept of generativity is a moral directive to *take care of* and to *care for and about* the development of others. As generativity is fully achieved and expressed in action, it will be linked to the prime adaptive ego quality of care (Leffel, Fritz, & Stephens, 2008). In contrast, experiences of stagnation are likely to be accompanied by the core pathology of rejectivity—a defensive, self-protective outlook. The person who develops rejectivity blames the target of envy and possibly justifies expressions of vengefulness or rage.

Care

The ego strength associated with the achievement of generativity is **care**.

> Care "is a widening commitment to take care of the persons, the products, and the ideas one has learned to care for. All the strengths arising from earlier developments in the ascending order from infancy to young adulthood (hope and will, purpose and skill, fidelity and love) now prove, on closer study, to be essential to the generative task of cultivating strength in the next generation, for this is indeed the 'store' of human life." (Erikson, 1982, p. 67)

Parenting contributes to the expansion of caring. Seven aspects of emotional development can be identified as potential consequences of parenting. First, parenting brings a depth of commitment that is tied to the responsibility for the survival of a child. This depth of commitment is strengthened through the reinforcing nature of the child's responses to attempts to meet his or her needs. Second, parenting brings adults into contact with new channels for expressing affection. Third, it requires that adults achieve a balance between meeting their own needs and those of others. Fourth, parenting enhances adults' feelings of value and well-being through the significant role they play in the child's life. Fifth, parents achieve a degree of empathy for their child that widens the array of their emotional experiences. Sixth, parents may experience new levels of emotional intensity in reaction to their child's behavior. Finally, many parents learn to help their children express and understand emotions. By playing a therapeutic role for their children, parents may become more effective in accepting and expressing their own emotions.

Parenting is not the only role through which adults experience the expansion of caring. A growing field of care-work jobs and careers contribute to the health, well-being, and development of others (Dwyer, 2013). A diversity of philanthropic organizations reflects this value in efforts to improve the quality of life and expand opportunities for others. The psychosocial achievement of middle adulthood is to identify the domains in which one has opportunities to influence the quality of the social environment so that it becomes more hospitable, humane, nurturing, or supportive of one's own visions for the future. Caring expands in different domains for different people, but it always leads to having the welfare of people and enduring things (including ideas) at heart. There is an action component to caring, in that people work to care for what they can. As the crisis of generativity versus stagnation is resolved in a positive direction, adults find new energy and innovative ways to express their capacity for care.

Rejectivity

Caring strongly for certain people, products, and ideas can cause people to reject any person or group that appears to threaten one's objects of care. **Rejectivity** refers to an unwillingness to embrace or include certain individuals, groups, or ideas in one's circle of care and, at an extreme level, to view these threats as appropriate targets for hostility, even annihilation. Ironically, one may exhibit great courage and dedication to protect the objects of one's care by directing intense aggression toward the objects that one rejects.

Erikson (1982) referred to this process as **pseudospeciation**, in which one defines another group as different, dangerous, and potentially less human than one's own. Seen through the lens of pseudospeciation, family members can become scapegoats, neighboring communities can establish intense rivalries, racial or religious groups can terrorize each other, and regions or countries can go to war. Albert Bandura (1999, 2015) has developed an analysis of how the core pathology of rejectivity and accompanying pseudospeciation can result in moral disengagement. By dehumanizing their victims or perceiving them as deserving of punishment, people can justify their cruel, harmful, and vicious behavior.

Thus, rejectivity goes beyond an intellectual selectivity of certain ideas and groups as more central to one's identity than others. It is transformed into harmful action, taking on an aggressive energy, drawn from the power and authority of one's status in middle adulthood. The risk of rejectivity for the society is that certain groups will become so powerful that they can cause the extermination or domination of other groups. Through control of the media, the legislature, the military, or the police, people in power can establish justifications for inhumane behaviors toward members of certain groups. As each subgroup falls out of the circle of caring, the society as a whole reaches a new level of stagnation.

FURTHER REFLECTION: *Describe the basic features of generativity and a generative outlook. Summarize the nature of a society in which the majority of adults are characterized as generative and contrast that to the nature of a society in which the majority of adults are characterized as stagnant.*

Explain why adults might resolve the psychosocial crisis of middle adulthood with a tendency toward stagnation. What are the implications for family, workplace, and community when adults with a tendency toward stagnation are in positions of authority?

Illustrate how creativity operates as a central process to resolve the psychosocial crisis of generativity versus stagnation.

Applied Topic: Discrimination in the Workplace

OBJECTIVE 6 Apply a psychosocial analysis to the issue of discrimination in the workplace, and evaluate the cost to society and to the individual when discrimination operates to restrict career access and advancement.

The United States has been characterized as an achieving society. As a cultural group, we value individual achievement, usually expressed through accomplishments in the world of work. In the United States, the mark of successful adulthood is frequently equated with success at work, which is typically attributed to personal characteristics of ability, intelligence, and motivation. Conversely, a lack of success in the labor market is attributed to deficiencies in personal characteristics—lack of ability, low intelligence, and poor motivation. Yet many Americans face serious and persistent disadvantages in the workplace that are linked to race, ethnicity, age, cultural practices, national origin, gender, sexual orientation, disability, or religion (MacLean, 2006).

Types of Discrimination

The following examples illustrate four areas of discrimination: sex discrimination, race discrimination, age discrimination, and discrimination based on disability.

Sex Discrimination

Promotion

Marilyn has worked as a sales clerk at a retail store for 10 years but has been repeatedly denied the opportunity to advance. Men with less experience, including men that she trained and/or supervised, received the promotions instead.

Pay

Carla worked her way up from the position of cook's helper to chef. Now another chef has been hired. He has similar training and work experience, but she finds out that he is being paid more than she is.

Sexual Harassment

Rita's boss is the vice president of the company. He repeatedly makes unwelcome comments about her body and routinely puts his arm around her waist when discussing work-related matters. Rita tells him his behavior makes her uncomfortable and asks him to stop. He says, "Maybe you are too uptight for this job. I probably should never have hired you." Now Rita is afraid of losing her job if she doesn't "loosen up." (equalrights.org, 2010)

Race Discrimination

Hoping to become lieutenants, 77 New Haven firefighters took a promotion test—but when none of the 19 Black firefighters qualified, the city jettisoned the results. Their hopes dashed, 17 White firefighters sued the city for racial discrimination, and the case went to the Supreme Court (newser.com, 2009). The Supreme Court found in favor of the White firefighters, stating that they were subject to race discrimination. The new standards announced by the Court will make it much more difficult for employers to discard the results of hiring or promotion tests once they are administered, even if the results have a disproportionately negative impact on members of a given racial group (Liptak, 2009).

Age Discrimination

Two years ago I worked at a nonprofit organization and was the oldest person employed in that facility as a teacher. It was an experience that will stay with me for the rest of my life. Working with people that thought of you as being too old to work with 3- to 5-year-old children was a nightmare. I endured being called an old lady that had no business being there and why would they hire someone that old? (about.com, 2010)

Disability Discrimination

An employer requires all job applicants to use an online recruitment portal. The portal is not accessible for people with visual impairments and you cannot use screen reading software with it. Unless the employer offered alternative ways for job applicants to apply, this would be indirect disability discrimination. (Equality and Human Rights Commission, 2016)

Overview of Discrimination

In the past, women and minority workers in the United States were restricted to low-paying jobs in the agricultural, service, or factory sectors. In 1964, the Civil Rights Act made it illegal to refuse to hire a person or discriminate in compensation, firing practices, or any other employment benefits based on race, color, religion, sex, or national origin. This act made the practice of restricting access to employment opportunities illegal and opened up many arenas for professional development that had previously been denied to minorities (Hodson & Sullivan, 2011). With additional legislation, other groups were included in the umbrella of legal protections. Currently, the U.S. Equal Employment Opportunity Commission (EEOC) lists types of discrimination to include age, disability, genetic information, national origin, pregnancy, race, religion, and sex-based factors including sex, gender identity, and sexual orientation. This office also addresses cases of retaliation against individuals who file charges of discrimination and cases of harassment including sexual harassment. The Civil Rights Act prohibits both intentional discrimination and otherwise neutral workplace policies that disproportionately disadvantage persons of a certain protected group (EEOC, 2016a).

Nonetheless, barriers to full and equitable involvement in the labor market for women, minorities, and persons with disabilities as well as persons in other protected groups continue to exist (Robert & Harlan, 2006). For example, some women find that their workplace sets limits on their achievement through gender-stereotyped assumptions about the woman's commitment to her family role (Ridgeway & Correll, 2004). In these settings, women do not tend to be promoted to high-level administrative or managerial positions in which work demands would begin to invade family commitments. Some companies are reluctant to put married women in positions in which they may have to be transferred for fear that their husbands will refuse to make the move.

In 2015, 89,385 charges of discrimination were filed with the EEOC (EEOC, 2016b). Retaliation was the leading cause of charges, almost 40,000 cases. Charges of discrimination on the basis of disability increased by 6 percent from the prior year, and were the third most frequent basis of discrimination after retaliation and discrimination on the basis of race. In addition to blatant discrimination in hiring practices, working conditions, salary, and dismissals, individuals have to cope with subtle acts of discrimination such as marginalization, harassment, and rumors or fictionalized stories that are embarrassing or imply that they are incompetent. Incivility and bullying are widespread problems that create a hostile environment for workers. National surveys indicate that 25 percent to 45 percent of workers report incidents of workplace bullying or harassment, often by supervisors, but sometimes by coworkers. Workers who are especially capable might be targeted for intimidation in hopes that they will quit (Barnes, 2012).

Workplace discrimination is an exceedingly costly problem for the society as a whole. Discriminatory practices that lead to the disaffection of individuals from the world of work is costly in economic terms—in lower levels of productivity, high turnover, high levels of irritability and conflict among workers, lawsuits, and less identification with the company and its goals. It is costly in personal terms as well. Workplace discrimination has both health and mental health consequences (Lim, Cortina, & Magley, 2008). Feelings of frustration about not being recognized for one's competence or being passed over for promotion by less competent workers interfere with the development of a generative orientation. These experiences may lead to a more self-serving orientation, focusing exclusively on self-protection or to a pervasive sense of futility about the future.

Disparities in Income and the Occupational Structure

The Equal Pay Act of 1963 "requires that men and women be given equal pay for equal work in the same establishment. The jobs need not be identical, but they must be substantially equal. It is job content, not job titles, that determines whether jobs are substantially equal . . . All forms of compensation are covered, including salary, overtime pay, bonuses, stock options, profit sharing and bonus plans, life insurance, vacation and holiday pay, cleaning or gasoline allowances, hotel accommodations, reimbursement for travel expenses, and benefits" (EEOC, 2016c). Nonetheless, disparities in salary, benefits, and other forms of compensation between women and men, and across racial/ethnic groups continue to exist, resulting in substantial differences in annual salary, rates of unemployment, and rates of poverty for people of comparable educational attainment by race and gender.

One explanation for the racial, ethnic, and gender differences in salary, rates of poverty, and rates of unemployment is that workers from different groups are distributed unevenly in the occupational structure. Jobs continue to be gender stereotyped, with women being socialized and encouraged to work in vocations that involve helping and serving others. In the food service industry, 70 percent of the waiter/waitress workers are women, but only 20 percent of the chefs and head cooks are women. In the health care industry, 73 percent of the physicians' assistants are women, but only 38 percent of the physicians and surgeons. Women are underrepresented as chief executive officers in corporations, architects and engineers, and the skilled trades where strong unions can protect salary scale and benefits (U.S. Bureau of Labor Statistics, 2016e). The wage gap can also be explained in part by the priority that different industries give to fixed versus flexible hours. In this context, women suffer, especially during their "childbearing and parenting" years. When industries reward time in the office or on the job, the wage gap between men and women is larger; when industries reward "getting the job done" and allow flexibility, the wage gap between men and women is smaller (Kliff, 2016).

Group differences in occupational position that result in different salary structures and risks of layoffs are not necessarily evidence of discrimination. Discrimination exists when two people doing the same job are paid substantially different wages. It occurs when factors other than merit prevent a person from being hired, promoted, or rewarded through various forms of compensation or increase a person's risk of being fired. Specifically, discrimination occurs when a person is evaluated on the basis of group membership rather than individual performance. In the workplace, this process operates as an in-group versus out-group dynamic, in which members of the in-group view members of the out-group as deficient and, at some level, possibly threatening to their own continued success and well-being.

In Miami Beach, Florida, these women are saying in no uncertain terms that for equal work they should receive equal pay.

How Discrimination Perpetuates Itself

Employers, supervisors, and others in positions of power typically establish a normative profile for their employees and judge each new employee against it. In some work settings, the judgment about competence is equated with a willingness to dedicate long hours to the job, be available at a moment's notice, and keep one's cell phone on at all times, including evenings and weekends. Gender stereotypes (beliefs about what men and women are like or should be like) can influence workplace decisions about hiring and promotions, as well as creating penalties or disadvantages when these stereotypes are violated (Heilman, 2012). In some instances, women who are mothers are expected to direct their time and energy toward their parenting role and, thus, are often judged to be less committed and less competent workers than women who are not mothers or than men who are fathers (Ridgeway & Correll, 2004). For example, in one study, participants rated women who were mothers as less competent—and thus less worthy of investing in hiring, training, or promoting them—than women who did not have children. Participants also rated women as less competent after they had children than before they became mothers (Cuddy, Fiske, & Glick, 2004).

These internalized norms about the ideal worker may include beliefs and values about the superiority of men in comparison to women. Men may wonder whether women can perform the same kinds of jobs as men and can effectively assume responsibility to supervise men, whether clients will place their trust in female executives, or whether women will be dedicated to their work when conflicts between work and family arise.

In the same vein, these norms may include beliefs and values on the part of Whites about people of color—especially beliefs that they are superior to people of color in ability, that the cultural characteristics of people of color will be disruptive or damaging to productivity in the workplace, or that people of color are better suited to some types of jobs than others (Feagin & McKinney, 2003). White men are twice as likely as men of color to be promoted to positions of authority and leadership (Cook & Glass, 2013). In many organizations, one can observe what has been called racial segmentation—the creation of specific kinds of administrative positions that were created to carry out affirmative action agendas, community relations with specific racial or ethnic communities, or to promote the recruitment of minority employees (Forman, 2003). Because of the historical and continuing separation of neighborhoods, schools, and churches on the basis of race, few White adults have firsthand, personal relationships with people of color. In many companies, promotions come about as a result of networks of contacts, which results in new opportunities and informal assessments of ability. Exclusion from personal and professional networks contributes to the continuing disadvantage of minorities. Decisions about promotions or assignments to positions of increased responsibility are often made in situations where senior employees, mostly White, make decisions that do not take into account the values, beliefs, and practices of non-White groups.

Consider the following situation: "FedEx's prohibition against individuals involved in customer contact from wearing dreadlocks, beards, ponytails or braids had been company policy for years but it was not enforced until 1999 when the Memphis, Tennessee-based company gave at least seven couriers who wore dreadlocks and worked in New York an ultimatum to cut them off or lose their jobs" (Cukan, 2001).

The employees were Rastafarians, who wear dreadlocks for religious reasons. They all offered to cover their hair with a hat or some other businesslike attire. However, FedEx refused this arrangement. The men were placed on a 90-day unpaid leave and then fired because no noncustomer contact positions could be found. These men had worked for FedEx for 5 years and had excellent service records with the company. The state of New York sued FedEx for violation of antidiscrimination laws, arguing that they fired the employees based on their religious observances. In response, FedEx changed its policy, allowing individuals to request an exception to the company's policy regarding hairstyles in order to respect their religious beliefs. This example illustrates the continuing need for examination of workplace practices that create hostile or disrespectful environments for workers.

Psychosocial Analysis: Discrimination and Coping

In general, in discussing psychosocial development, one examines the outcome for the individual in achieving a positive resolution of the psychosocial crisis. But when considering discrimination in the workplace, one must also look at the consequences for a society. Discrimination in the workplace is one expression of *societal stagnation*. It is a defensive posture, in which those in power try to protect their own status and profits by preventing members of less powerful groups from gaining a foothold. Rather than treating diversity as a factor that can improve productivity in the work setting, discrimination operates to reduce it.

Over time, the fate of individuals who have been discriminated against becomes a great cost to the society at large. Perceived discrimination in the workplace has been associated with lower job satisfaction, reduced life satisfaction, health problems, depression, and general anxiety (Feagin & McKinney, 2003; Jang, Chiriboga, & Small, 2008). Some targets of discrimination give up and become chronically unemployed or underemployed, resulting in a loss of human capital. Others remain in a discriminatory workplace, trying to get by, not making trouble, and yet operating behind a veil of caution.

Two approaches to reducing the impact of discrimination have been described as identity switching and identity redefinition. Identity switching involves concealing or deemphasizing the stigmatized identity and emphasizing a more valued identity. A gay worker might try to conceal his sexual orientation at work, and engage coworkers in conversations about his attachment to his college or his hometown. Identity redefinition involves highlighting the positive or valued aspects of one's social identity rather than those that are devalued. A woman who is aware of the negative assumptions that women are not good at math and science might try to emphasize her communication and negotiation skills in the workplace. Rather than concealing their identity, people may try to convey the strengths or benefits of their group membership. These two strategies can be effective in deflecting hostile or discriminatory practices, but they can also be costly in terms of the psychological energy needed to preserve the altered identity and in social isolation from others in one's stigmatized group (Shih, Young, & Bucher, 2013). One outcome of the various forms of discrimination is the development within a person of an unspoken resentment of work that may be communicated in some form to one's children, thus transmitting a cross-generational, cynical outlook on work.

However, the history of the United States is also filled with many cases of individuals who succeed against the odds. Adults recognize the risks of staying in a setting that does not fit well with their desire to create, produce, and care. They may strike out on their own by setting up their own companies, they may challenge unfair practices through the courts, and they may mentor younger workers to help them cope with the conflicts they face in the workplace.

The responsibility for coping with discrimination cannot rest entirely on its victims. There are examples of work settings that have taken active steps to challenge their own practices. Company policies that value diversity and multiculturalism can be conveyed in their mission statement, their training of managers and supervisors, and in the images they use in their promotional materials, corporate events, and hiring and promotion practices. Companies have been recognized for their policies to support the hiring and promotion of women into senior positions, and for their innovations in weaving new levels of understanding about diversity into all aspects of employee development. A growing focus on corporate social responsibility suggests that many companies strive to go beyond compliance with the law to engage in practices that reflect high ethical standards and address specific aspects of community welfare. These practices can benefit the reputation of the company, but they also create a positive workforce identification and sense of attachment to the workplace (Bauman & Skitka, 2012). Companies are recognizing that by being more visibly attuned to the interests and needs of culturally diverse communities, they can increase their brand reputation and increase their client base (Purdie-Vaughn, Steele, Davies, Dilmann, & Crosby, 2008; Rodriquez, 2006).

The American workforce of the 21st century is becoming increasingly diverse. Women and ethnic minorities are the fastest growing groups of new employees. Slightly more than 25 percent of children who were under the age of 5 in 2009 were children of color (U.S. Census Bureau, 2012a, Table 10). Their preparation for and participation in the labor market will be determining factors in the quality and productivity of the U.S. economy in the years ahead. The psychosocial approach, which highlights the interdependence of the individual and the society, is dramatically illustrated in the connection between contemporary workplace policies and practices and their implications for the maturation of a sense of initiative and industry during childhood. Children who believe that their parents and other adult members of the community are thriving in work environments that respect and value them are more likely to make the commitment to schooling that is needed to participate fully when it is their turn to enter the labor market.

FURTHER REFLECTION: *Define the concept of workplace discrimination. List the various forms of discrimination that can arise. Describe the evidence you have seen of discrimination in the settings where you work, where you attend school, or where you function as a consumer.*

Investigate factors that are associated with workplace discrimination. What personal, cultural, or societal factors might account for workplace discrimination? What might motivate individuals to harass, undermine, or reject their coworkers?

Based on your understanding of psychosocial development, predict what kinds of experiences in earlier stages of life might protect a person from the negative impact of discrimination and foster effective coping.

CHAPTER SUMMARY

During the middle adult years, people have an opportunity to make significant contributions to their culture. Through work, home, childrearing, and other caring relationships, people express their own value orientations, moral codes, personalities, and talents. They grow more sensitive to the multiple needs of those around them and more skillful in influencing the social environment.

OBJECTIVE 1 Analyze features of the world of work as a context for development, focusing on interpersonal demands, authority relations, and demands for the acquisition of new skills.

The developmental tasks of middle adulthood are complex and require long-term persistence. People gauge their self-worth largely in relation to their contributions to complex social units, especially work, family, and community. Each task calls for a new level of conceptualization of the interaction of the self with immediate and more remote social systems and an increased ability to balance one's individual needs with system goals.

In the process of managing a career, one observes the bidirectional influence of individuals and their work settings. Occupational environments have an impact on the cognitive, interpersonal, and emotional development of middle adults, and middle adults influence work settings through their positions of authority, leadership, and the achievement of new levels of expertise. Effective leaders try to balance the good of the group with their own self-interest. They try to take into account the best interests of individuals, groups, and communities while they also participate and lead. The requirements of leadership may change as the group develops and as the team or organization faces new, emerging challenges.

The concept of interpersonal skills is complex and includes at least three components: self-presentation, or how a person introduces oneself to others and conveys openness to further interactions; social scanning, or the ability to read the social cues in the situation; and social flexibility, or the ability to respond adaptively to the social demands of the situation, for example by being assertive or cooperative as the circumstances require.

A key area of skill development in the contemporary labor market is *creative problem solving*. The combination of increasingly complex technology, instant international communication, and continuing reorganization of the network of interrelated businesses results in the emergence of a new and changing array of problems. The concept of managerial resourcefulness captures the nature of this problem solving. Managerial resourcefulness combines three critical features: a cognitive capacity to gather and analyze information, sensitivity to the emotional and motivational aspects of change, and a readiness to take appropriate actions.

One of the significant challenges of middle adulthood is the effective coordination of work and family life. Three concepts are reviewed: role overload, role conflict, and spillover. Role overload in the workplace is consistently perceived as a source of stress and is typically associated with negative attitudes toward the organization, reducing a worker's organizational commitment and job satisfaction. Although much of the responsibility for managing multiple roles falls to individuals and couples, work–family facilitation can be supported by resources and policies in the workplace that make it easier for employees to address pressing family demands within the scope of their daily work.

OBJECTIVE 2 Define the concept of a vital, intimate relationship and examine factors that support this goal in middle adulthood, especially a commitment to growth, effective communication, creative use of conflict, and preserving passion.

Happiness in an intimate relationship is a cornerstone of well-being in middle adulthood. The establishment and preservation of close, nurturing relationships require ego strengths of the partners, effective communication strategies, a commitment to the future of the relationship, and creative strategies for preserving passion and excitement within a framework of close companionship. Long-term stable relationships are typically based on a strong bond of friendship. The partners support each other and like each other. They have shared interests, enjoy similar activities, and are supportive and appreciative of one another's accomplishments. A vital marriage requires both partners to be open to the need to be themselves (as they continue to discover new dimensions of self) and an energizing, interpersonal chemistry that is resilient even in the face of the harshest challenges. Partners in an enduring relationship repeatedly act in ways that take into account their own self-interest and the well-being of their partner.

OBJECTIVE 3 Evaluate the expansion of caring in middle adulthood as it applies to two specific roles—that of a parent and that of an adult child caring for one's aging parents. Clarify your assumptions about the costs and benefits of enacting these roles.

The maturity and commitment to care of those in middle adulthood are closely linked to the psychosocial well-being of children as well as the elderly. Through parenting, adults create the supportive environment for children's safety, health, and development. The parents' personalities, their attachment orientations, the quality of their shared parenting activities, and the infant's temperament all contribute to the quality of this alliance. The quality of the parental alliance provides the model that children observe and internalize as they conceptualize the nature of adult relationships. The demands on adults as parents change as children mature. With each stage of family life, adults experience new opportunities for growth that are stimulated in part by their children's new capacities and relationships, as well as by the settings that link parents, children, and their activities.

Through their relationship with their aging parents, adult children can support their parents' optimal functioning and, at the same time, grow in their understanding of the challenges of aging. **Filial** obligation is a feeling of responsibility to care for one's parents; a sense of responsibility that adult children have to help their parents as they get old, especially when their physical or mental health declines; or a moral sense of duty that arises as one realizes and acknowledges the sacrifices one's parents have made and the sense of indebtedness for those sacrifices. Aging parents and adult children may have different ideas about how to enact filial obligation. Effective communication is a key to preserving positive relationships when goals and views about providing care conflict.

OBJECTIVE 4 Summarize the tasks required for effective management of the household and explain why they are necessary. Describe the diversity of households, including blended families, single-parent families, and adults who live alone, and hypothesize about the implications of these various household structures for individual development.

Management of the household involves the creation of a safe, stimulating, and comforting environment for those who live there. The capacity to maintain a household and nurture those who live there is linked to the middle adult's ability to identify needed resources and to create the network of relationships that will support the members of the household. The skills that are needed to achieve these goals will differ depending on the structure of the household and the ages, abilities, and relationships of the household members. In addition to the two-adult family with children, alternatives that are described include blended families, single parent families, and people who live alone. The topic of homelessness is highlighted as a particular challenge in the context of the importance of home in middle adulthood.

OBJECTIVE 5 Define and explain the psychosocial crisis of generativity versus stagnation and the central processes through which the crisis is resolved: person–environment interaction and creativity, the primary adaptive ego strength of care, and the core pathology of rejectivity.

The psychosocial crisis of the middle adult years—generativity versus stagnation—is really a moral crisis of commitment to a better way of life. The well-being of the community as a whole rests largely on the effectiveness of people in middle adulthood in reaching new levels of psychosocial maturity. The society must encourage adults to care for others besides themselves. The egocentrism of toddlerhood, early school age, and adolescence must eventually come to an end if the social group is to survive. In the same way that intimacy (giving oneself to another) requires identity, generativity (giving oneself to the next generation) requires love of specific others. Interpersonal sources of satisfaction are the primary forces propelling people toward a generative approach to society as a whole.

As generativity is fully achieved and expressed in action, it will be linked to the prime adaptive ego quality of care, a capacity to look after and promote the optimal development of others. In contrast, experiences of stagnation are likely to be accompanied by the core pathology of rejectivity—a defensive, self-protective outlook in which self-interest and self-aggrandizement are heightened by devaluing or degrading others.

OBJECTIVE 6 Apply a psychosocial analysis to the issue of discrimination in the workplace, and evaluate the cost to society and to the individual when discrimination operates to restrict career access and advancement.

The applied topic of discrimination in the workplace provides evidence of societal stagnation. Laws have been enacted to protect members of specific groups from discriminatory practices, and regulatory agencies are charged with the monitoring and prosecution of unlawful practices. Nonetheless, discrimination in the workplace continues, along with retaliation against those who file complaints and harassment of workers by supervisors and coworkers. Often, it is middle adults in leadership positions who, by deliberate practice or informal example, set a tone that promotes the exclusion of certain workers on the basis of age, gender, racial or ethnic group, ability status, or other group characteristics. At the same time, others in middle adulthood suffer from discriminatory policies and are unable to reach the levels of achievement and contribution that their talents merit. Social policies and practices that interfere with individuals' abilities to perform meaningful work or to achieve recognition and respect for their work pose a hazard to individual psychosocial development and to the future of the social group. These practices, born from the core pathology of rejectivity, act in opposition to the fundamental needs of a society to care about its members and foster the most optimistic ambitions and goals possible in younger generations.

CASEBOOK

For additional case material related to this chapter, see the case of "Annie and Career Contemplation," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 176–179. In this case, Annie evaluates her current work situation in light of health concerns and a desire for greater personal satisfaction.

akg-images/akg-images/Superstock

The integrating theme of later adulthood is a search for personal meaning. When older adults achieve a sense of integrity, it leads to inner peace and serves as a source of reassurance to the next generation.

LEARNING OBJECTIVES

1. Examine the construct of life satisfaction in later adulthood and analyze factors associated with subjective well-being.
2. Define intellectual vigor, and describe factors that promote it in later life. Evaluate evidence about the interaction of heredity and environment on intelligence in later life.
3. Explain the process of redirecting energy to new roles and activities, with special focus on role gain, such as grandparenthood; role loss, such as widowhood; and new opportunities for leisure.
4. Summarize the development of a point of view about death.
5. Define and explain the psychosocial crisis of integrity versus despair, the central process of introspection, the prime adaptive ego quality of wisdom, and the core pathology of disdain.
6. Apply theory and research to understanding the process of adjustment to retirement.

Chapter Summary

— CASE STUDY Reflections on Retirement —

Mary Gergen is Professor Emerita of Psychology and Women's Studies at Penn State University, Brandywine and co-founder of the Taos Institute, focusing on the integration of social constructionist ideas and professional practice. Here she reflects on the experience of retiring.

Younger people believe that health is something one takes for granted. Middle aged people worry as they start to see chinks in their armor, but older people learn to adjust. By and large, people manage to live well, even with major decrements in their youthful capacities. It is a good idea to eat well, sleep long, and laugh heartily in one's career days as extra insurance against falling apart too soon. Keeping up good habits helps in retirement as well.

Overall, life is not that different for me today from what it was ten years ago: I don't envy people who have a full time job at all. I often wonder why some people are still carrying the burdens of fulltime employment when they don't really need to. It's snowing out right now, and the highway is packed with cars going about 10 miles an hour. In those cars are people going home from work, tense and tired, and eagerly awaiting the chance to kick off their shoes and relax with their loved ones. (At least that is my fantasy.) And here I am, writing up the joys of not being out there, struggling to get home. I'm already home. (Gergen, 2012, pp. 307–308)

CASE ANALYSIS Using What You Know

1. Based on what you have read about the nature of work and career development, explain how the concept of retirement might be viewed differently and have different meaning depending on one's stage of life, including early adulthood, middle adulthood, and later adulthood.
2. Speculate about how retirement contributes to Mary's sense of control over her life and general well-being.
3. List some reasons why people might continue to work well into their later adulthood. Explain how work might contribute to life satisfaction, personal identity, health, and financial and psychosocial well-being in later life. How might continuing to work undermine these domains?

In this chapter and the next, we consider the challenges, changes, and new avenues for development in later life. This chapter focuses on the period from 60 to 75; the next chapter focuses on the years from 75 to the end of life. The French refer to the years from 60 onward as the troisième age, the third stage of life (Rubenstein, 2002). One can think of the first 30 years of life as a period of construction and learning, when many avenues are open and the person is building the skills and knowledge to engage in the roles of adulthood. The second 30 years, from 30 to 60, are a period of enactment, when commitments established during identity formation are translated into roles and relationships. In this period, life is shaped by the interaction of work, family, and community demands and expectations. The individual strives to achieve personal ambitions and goals and to meet cultural expectations for maturity while coping with planned and unexpected changes in adjoining systems. The final 30 years are a period of reinvention. The integrating theme of later adulthood is a search for personal meaning. For many, this stage of life brings a gradual release from the daily demands of work and family and, depending on one's health and resources, provides the opportunity to invent a new life structure. This is a time when one faces both significant adversity and great joy.

Psychosocial theory assumes that new opportunities for growth emerge at each life stage. Like each of the preceding stages, later adulthood is marked by stressors, risks, and forces that can disrupt growth. However, in strong contrast to the stereotype of aging as an undesirable process associated with accumulated deficits and decline, these chapters highlight continuous growth through coping and adaptation.

One cannot understand the full unfolding of human life without appreciating the beliefs, practices, and social relationships of those in later adulthood and old age. The interdependence of the stages in a human life story suggests that the ways in which older adults function and are treated will have immediate impact on the psychosocial development of individuals in all the earlier periods of life. The courage and vitality of older adults are sources of inspiration that motivate children and younger adults to continue facing the challenges of their lives with optimism.

Physical, social, emotional, and intellectual developments are intricately interrelated during later life. Patterns of aging are neither universal nor irreversible. For example, although many older adults become more sedentary and lose aerobic capacity, others continue to perform strenuous labor and remain free from heart disease and respiratory difficulties. Many life conditions, especially poverty, malnutrition, poor sanitation, and limited health care, can accelerate the aging process. Other life conditions, such as access to a stimulating social environment, participation in a program of physical activity, and a well-balanced diet, can increase physical and intellectual functioning (Jeste, Depp, & Vahia, 2010; Rowe & Kahn, 1998). It is essential to keep in mind the individual differences in physical and mental health when thinking about patterns of growth in later adulthood.

Most of the people in today's cohort of later adults are part of the baby boom generation (born between 1945 and 1964). At the close of World War II, there was a spike in the birthrate over a period of 14 years resulting in a substantial increase in the population. Because of its size, the baby boom generation put pressure on many social institutions, pushing for more resources at every stage of its development including building new elementary schools, new high schools, community colleges, and increasing competition for college enrollment.

This cohort grew up in a time of national optimism following the close of the war and economic prosperity in the 1950s. It was a time of remarkable contradictions. Competition with the Soviet Union brought about the space race resulting in landing humans on the moon and the expansion of space exploration. This same political tension resulted in the Cold War, fear of communism, and threats of a nuclear attack. Coming of age in the 1960s and early 70s, this cohort faced the challenging social and political issues associated with the war in Vietnam with accompanying protests and devastating loss of life, the civil rights movement, the hippie counterculture, and the assassinations of John F. Kennedy, Robert Kennedy, and Martin Luther King, Jr. (Robinson, 2016).

In the context of the sexual revolution and the women's movement, baby boomers resumed the trend to delayed age of marriage which was noted at the start of the 20th century. They experienced an increase and destigmatization of divorce, and had smaller families. These changes have led some to wonder who will meet the social support and care needs of the baby boomers as they age. As they enter later adulthood, they are putting new pressures on the health care system, the Social Security system, and the demand for new leisure, education, and community services. Having challenged social institutions over the course of earlier life stages and innovated in family, work, and community contexts, the baby boomers are redefining the nature of later adulthood including new ideas about continuing education, work, retirement, and family life.

For people in the United States who were 65 years old in 2014, the average life expectancy was an additional 18 years for men, and an additional 20.5years for women (National Center for Health Statistics, 2016a, Table 15). Major improvements in hygiene, nutrition, preventive medicine, and medical treatments and technologies have allowed more people to experience a vigorous later adulthood today than was true 70 years ago. As a result, more and more people are living to face the developmental tasks of later adulthood and elderhood. ●

Developmental Tasks

The developmental tasks confronted in later adulthood include: accepting one's life and achieving a sense of life satisfaction, promoting intellectual vigor, redirecting energy to new roles and activities, and developing a point of view about death. These themes suggest new barriers to adaptation as well as new opportunities. Changes in memory and reduced speed of neural processing may make the accomplishment of daily tasks more difficult. Role loss and the death of loved ones stimulate needs for new kinds of support and changes in daily lifestyle. Success in these tasks requires considerable psychological effort. As the more structured roles of parent and worker become less demanding, a person has to find new sources of personal meaning and a new pattern to daily life. In some cultures, aging takes place in a context of reverence and high regard, which makes the loss of certain instrumental activities less significant. In other cultures, emphasis on autonomy, instrumentality, and achievement form a challenging context for the preservation of dignity in late life.

Accepting One's Life

OBJECTIVE 1 Examine the construct of life satisfaction in later adulthood and analyze factors associated with subjective well-being.

One of the significant challenges of aging is learning to accept the reality of one's life and formulate a vision of this new phase of later adulthood.

> "Weren't you ever afraid to grow old?" I asked.
>
> "Mitch, I *embrace* aging."
>
> "Embrace it?"
>
> "It's very simple. As you grow, you learn more. If you stayed at twenty-two, you'd always be as ignorant as you were at twenty-two. Aging is not just decay, you know. It's growth. It's more than the negative that you're going to die, it's also the positive that you *understand* you're going to die, and that you live a better life because of it." (Albom, 1997, p. 118)

By later adulthood, evidence about one's successes and failures in the major tasks of middle adulthood—marriage, childrearing, and work—has begun to accumulate. Data by which to judge one's adequacy in these areas are abundant. The process of accepting one's past life as it has been may be a difficult personal challenge. One must incorporate certain areas of failure, crisis, or disappointment into one's self-image without being overburdened by a sense of inadequacy. Individuals also must be able to take pride in areas of achievement, even when those accomplishments fall short of personal expectations. At the same time, older adults face the challenge of defining new goals for the future.

We have used the language of "accepting one's life" as a developmental task for later adulthood. This language reflects the reality that many people experience some disappointment, regret or frustration in their middle adulthood at being unable to achieve the hopes and dreams that they may have set for themselves at earlier ages (Rauch, 2014).

> K. is a 54-year old woman [who] had an exciting launch in her 20s ("working my dream job"), a sense of continuing achievement but slowing momentum in her 30s ("sort of a slog"), and an ambush in her 40s, when her father died, her mother had a stroke, her husband left her after their daughter was born, and she was laid off. Despite coping with all of that and doing well professionally, even with her layoff ("I did better in my career; I made more money") she developed what she describes as a dark sense of humor about her life, ruefully telling herself that at least she had so many troubles that she couldn't dwell on all of them at once. (Rauch, 2014, p. 9)

The challenge facing later adults is to accept their disappointments, to view the life they have led with satisfaction, and to find meaning and purpose in the life they have yet to live. Much of the literature on successful or positive aging includes terms such as well-being, life satisfaction, and happiness to examine how well older adults are able to attain this state of acceptance and positive outlook. Studies differ in the way these concepts are defined and measured (Martin et al., 2015). Table 13.1 provides definitions of successful aging from six sources, giving a sense of the variety of dimensions that might be included under this conceptual umbrella. From these definitions, you can appreciate that successful aging is a biopsychosocial process. The discussion that follows describes several models for understanding how older adults establish a satisfying approach to the developmental task of accepting one's life in light of changing resources, goals, and accomplishments.

Table 13.1 Definitions of Successful Aging

Author	Definitions
Baltes & Baltes, 1990	Selective optimization with compensation
Depp & Jeste, 2006	Disability/physical function, cognitive functioning, life satisfaction/well-being, social/productive engagement, presence of illness, longevity, self-rated health, personality, environment/finances, self-rated successful aging
Kahana & Kahana, 1996, 2003	Social and psychological resources, preventive and corrective adaptations, psychological, existential, and social well-being

The SOC Model

Over the life span, people confront the challenges of balancing and matching a variety of opportunities with fluctuations in resources (Baltes & Baltes, 1990; Freund & Baltes, 1998). At every period of life, there are limited resources—whether time, energy, or money—to address all the opportunities that present themselves. For example, in later adulthood, a person may want to continue to work (an opportunity) but find that a chronic heart condition makes it difficult to bring the required energy and resilience to the task (loss of a resource). According to the **SOC model**, adaptation requires the integration of three processes:

Selection: Identifying the opportunities or domains of activity that are of the greatest value or importance.

Optimization: Allocating and refining resources in order to achieve higher levels of functioning in the selected domains.

Compensation: Under conditions of reduced resources, identifying strategies to counteract the loss and minimize the negative impact on functioning in the selected domains.

In later life, adults are inevitably faced with changes in resources. They may have more time, but less physical stamina and fewer financial resources. Life satisfaction and a sense of well-being are linked to selecting specific goals as important areas of functioning and then effectively directing both internal (e.g., energy, thought, planning) and external (e.g., hiring help, taking classes, technical assistance) resources in order to maximize their level of functioning. Demographic factors alone—such as gender, race, age, and income—are not adequate predictors of life satisfaction. Instead, well-being rests on two related coping strategies: (1) An ability to anticipate potential losses and prevent them through proactive coping in order to prolong the availability of resources and maintain engagement with desired activities (Ouwehand, de Riller, & Bensing, 2006) and (2) an ability to manage or reduce the impact of stressful life events by redirecting resources in order to continue engaging in valued roles and activities (Hamarat et al., 2001; Salvatore & Sastre, 2001). For example, preventive adaptation can include purchasing a stationary bicycle to support daily aerobic exercise, especially if you live in a climate that makes outdoor exercise difficult in extreme heat or freezing weather. Knowing that older adults can be the target of financial scams, people can reduce the impact of these stressors by having a reliable contact like an adult child, grandchild, or financial professional to contact when in doubt about a phone or email request for personal or financial information. Building in time to relax each day can help reduce the toll of daily stress on physical and mental health.

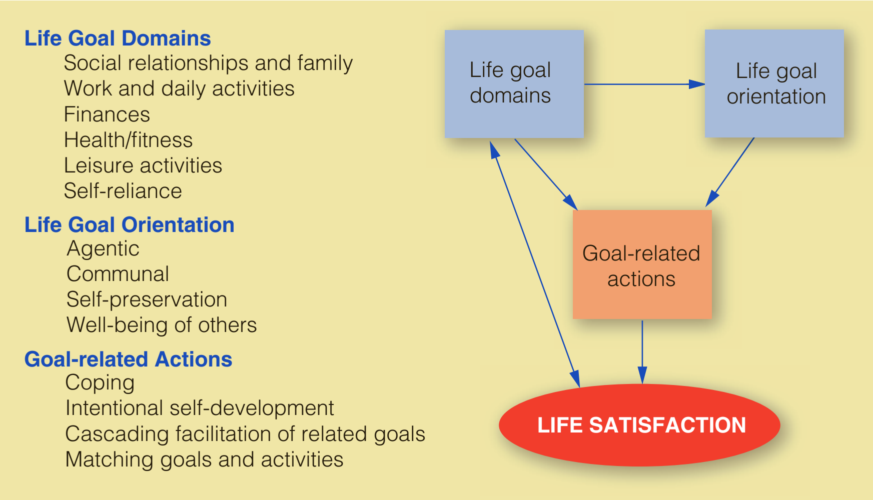
Life Goals and Life Satisfaction

Life satisfaction is an overall assessment of feelings and attitudes about one's life, rather than a momentary feeling of happiness or unhappiness. It can be assessed as a global overview (e.g. "How satisfied are you with your life at present?") or as a composite of satisfaction with various domains such as work, leisure activities, social/family life, health, and finances/income (Kapteyn, Smith, & van Soest, 2009). Many older adults have high levels of life satisfaction even though they face serious stressors and physical limitations (Brandtsadter, 2002). In part, this is due to their ability to achieve or realize important personal goals, and in part it is due to the ability to modify or adjust their goals in light of changing resources. Goals are linked to daily actions, related to desired states in the present or the future, and controllable, at least in so far as the person can choose to invest resources in certain goals or not (Mayser, Scheibe, & Riediger, 2008).

In later adulthood, individuals continue to aspire to new goals and strive to achieve new levels of optimal functioning. A person's life goals and needs may change over the course of later adulthood, depending on life circumstances. Rather than viewing satisfaction in later adulthood in terms of wrapping things up and facing a roleless, undifferentiated future, older adults continue to formulate personal goals and assess their current life satisfaction in light of how well they are able to achieve those goals. In order to appreciate the link between life goals and life satisfaction, it is important to consider three aspects of life goals: goal domains, **goal orientation**, and goal-related activities that are aligned with achieving valued goals (see FIGURE 13.1 ▶).

Goal Domains.

What are the achievements that stand out as important areas of accomplishment in later adulthood? Studies of life goals and life satisfaction present different typologies of life goals. One international study of life goals compared older adults in the United States and Holland. Four domains were relevant to both groups: job or daily activity goals, social contact and family goals, health goals, and income goals. Across the two cultures, attainment of social contact and family goals were the strongest



Life Goal Domains
Social relationships and family
Work and daily activities
Finances
Health/fitness
Leisure activities
Self-reliance
Life Goal Orientation
Agentic
Communal
Self-preservation
Well-being of others
Goal-related Actions
Coping
Intentional self-development
Cascading facilitation of related goals
Matching goals and activities
Life goal domains
Life goal orientation
Goal-related actions
LIFE SATISFACTION

predictor of overall life satisfaction (Kapteyn, Smith, & van Soest, 2010). Other studies include self-reliance or autonomy goals and leisure time and physical activity goals in their analyses of the link between life goals and life satisfaction (Straechen, Brawley, Spink, & Glazebrook, 2010; Wong & Lou, 2010).

Individuals show different patterns of investment in these **goal domains**, and in the specific activities or achievements within domains. To some extent, a person's profile of meaningful goals takes shape in the stages of later adolescence and early adulthood. At that time, individuals are crystallizing their identity and creating a lifestyle. The combination of one's culture and life experiences shapes an imagined self, moving into the future. As a person begins the process of accepting one's life in later adulthood, there is a tendency to return to the personal goals that were envisioned at that earlier time of life in order to assess the extent to which they were realized and perhaps to reevaluate their importance given the 40 years or more of life that have transpired since these goals were formed (Cappeliez, 2008).

Goal Orientation. In addition to the specific goals one aspires to, people differ in their goal orientation. Some people are more agentic in their goal strivings. Their important goals focus on achievement, power, and the expression of personal abilities. Other people are more communal in their goal strivings. Their goals focus on intimacy, affiliation, and contributions to the moral community (Pohlmann, 2001). Other studies have contrasted goals that seem to emphasize self-preservation with those that focus on the interest in and well-being of others. One might look back at the psychosocial crisis of middle adulthood, generativity versus stagnation, and consider that the profile of goals emerging from that period of life might differ for those who resolved the crisis in the direction of generativity compared to those who resolved it in the direction of stagnation (Lapierre, Bouffard, & Bastin, 1997).

Goal-Related Actions. As people make progress on the developmental task of accepting their life, they are able to integrate their goals and their **goal-related activities** in order to experience a sense of personal fulfillment. For those in later adulthood who have a strong sense of self-directed goal attainment, sentiments of life satisfaction feed back into life goals, strengthening their sense of purpose and providing renewed energy. Activities that are not satisfying or that bring negative social exchanges will be abandoned in favor of activities that are enjoyable and that contribute to feelings of confidence or well-being. With age, it appears that a person's goals become more supportive of each other, so that one activity, for example, joining a book club, can provide support for both intellectual goals and social goals; spending time with grandchildren can be an opportunity to experience family support and physical activity. Couples who enjoy cooking may find that this shared interest also allows them to spend time together, planning, shopping, and preparing meals. Older adults find that their goals

Ray and Carla have more time for each other now that they are getting closer to retirement. Their happiness as a couple is an important source of life satisfaction. A shared interest in cooking combines physical activity, cognitive planning, cooperative efforts, and enjoyment of the results.

support each other and that they can invest more energy into personal goal pursuits as their obligations to other competing roles and role demands decline (Riediger, Freund, & Baltes, 2005). The more closely a person is able to match activities with valued goals, the greater the life satisfaction (Halisch & Geppert, 2001). As the case of Orville Brim's father illustrates, many of the basic motives for goal pursuits may remain the same over time, but the implementation of specific activities may change as a person's physical health or endurance declines with advanced age.

— **CASE STUDY** Goal Adjustment in Later Adulthood —

Orville Gilbert Brim, who contributed to the field of human development through his work on social role theory (see chapter 3), became increasingly interested in ambition and self-directed goal attainment in adulthood. He described his father's successful adaptations in later life as an example of this process (Brim, 1992).

Brim's father, also named Orville, lived to be 103. He was born in a small farming community in a rural area of Ohio in 1883. After receiving his bachelor's degree in education at Valparaiso University, he taught school in a one-room schoolhouse for 2 years and then became principal of a high school in Indiana. Eventually he left the rural Midwest to attend Harvard and then Columbia to get his PhD. He was a professor at Ohio State University until he retired at age 60. Then Orville and his wife, Helen, bought an abandoned farm of several hundred acres in Connecticut, remodeled the farmhouse, and settled into farming. In the early years of retirement, he cleared and thinned the trees on the hills and mountains of his farm. After a while, he stopped working the hillsides and planted a large vegetable and flower garden. Orville tilled the garden with a power tiller. When he was 90, he bought a riding tractor. When he could no longer manage the large garden, he focused on a small border garden and four large window boxes that he planted with flowers. As his eyesight became more impaired, he shifted from reading to listening to "talking books," and when he had to give up actually planting the window boxes, he enjoyed watering them and looking at the flowers. Orville approached each new challenge of physical decline by correctly assessing his abilities, investing in a new project, and taking pride in his achievements within that domain.

CASE ANALYSIS Using What You Know

1. In this case, Brim's father drew on early life experiences growing up on a farm to guide his goals in later adulthood. Describe how a person might integrate other prior life roles into a satisfying lifestyle in later adulthood.
2. Explain how goal readjustment is related to life satisfaction in this case. Analyze some of challenges people might face in later life as they realize the need to revise their life goals.
3. Describe the resources Brim's father had that allowed him to achieve new goals for mastery.

Social Integration and Well-Being

A basic element in life satisfaction is the sense of belonging, a fact that has been supported by a wide range of research across life stages (Baumeister & Leary, 1995). In later life, social relationships are a primary source of pleasure and meaning and are an avenue for active engagement. People who experience loneliness or an inadequate social network are much less satisfied with life than those who perceive themselves to be positively connected to a meaningful circle of loved ones and friends (Gow et al., 2007). In the context of marital relationships, high levels of conflict are associated with depression and lower life satisfaction for both men and women (Whisman et al., 2006). Even though social connection is a source of life satisfaction in later adulthood, negative relationships and ongoing exposure to interpersonal conflict can disrupt feelings of satisfaction.

In a longitudinal study, men who had participated in the Terman Study of Gifted Children when they were in early childhood were interviewed about their life satisfaction at ages 58 to 72. Four styles of adaptation emerged: (1) poorly adjusted, (2) career focused but socially disengaged, (3) family focused, and (4) well rounded. Three family experiences from early childhood and adolescence, including parent–child attachment, family socioeconomic status, and early parental divorce, were associated either directly or indirectly with life satisfaction in later life (Crosnoe & Elder, 2004). In addition, contemporary factors including health and socioeconomic resources were generally predictive of life satisfaction for the group as a whole. Goals related to family life and religious life provided a greater sense of meaning, social benefits, and emotional support than occupational goals, especially for the family-focused and well-rounded groups (Crosnoe & Elder, 2002b). The family-focused and well-rounded groups had many areas of similarity, as did the career-focused and poorly adjusted groups. There is some suggestion that people who place too great a priority on occupational attainment during middle adulthood may find it difficult to reorient toward satisfying life goals in later adulthood.

Personality and Well-Being

We all know people who have lived difficult lives yet appear to be full of zest and enthusiasm. We also know people who appear to have had the benefits of many of life's resources yet are continually complaining about problems. Whether specific events will contribute to feelings of satisfaction or dismay depends in part on how they are interpreted. Some people are more likely to be grumblers; others are more likely to be celebrants of life. In efforts to understand these differences, some researchers have looked to personality factors to predict subjective life satisfaction in later adulthood.

The term **personality** refers to patterns of thoughts, feelings, and actions that are characteristic of a person across situations. Personality provides ways of understanding individual differences in coping, goal orientation, and self-evaluative processes. Confusing as it may seem, personality is both stable and changing over one's life. Personality is stable in the sense that people who are high in one aspect of personality in comparison to their peers remain relatively high in that quality over time. For example, a person who is outgoing and sociable in comparison to others will continue to rank high in sociability over time. Personality is also changing in the sense that certain personality qualities seem to increase with age, while others decline. For example, studies find that agreeableness increases with age, whereas openness to new experiences declines (Lodi-Smith, Turiano, & Mroczek, 2011).

A number of personality characteristics have been linked with life satisfaction in later life, including extroversion, openness to experiences, lack of neuroticism, usefulness/competence, optimism, a sense of humor, and a sense of control. **Extroversion** includes such qualities as sociability, vigor, sensation seeking, and positive emotions. People who are outgoing and enjoy social interaction tend also to report high levels of life satisfaction (Costa, Metter, & McCrae, 1994). In a comparison of two cohorts of older adults, those assessed in 1976–1977 and those assessed in 2005–2006, the more recent group of older adults were more extraverted and less constrained by social desirability, suggesting a generational shift toward a more outgoing, trusting interpersonal style (Billstedt et al., 2013).

Openness to experience includes characteristics such as curiosity, imaginativeness, and enthusiasm about exploring different music, art, foods, travel, or points of view. Older adults who are open to new ideas and are aware of their feelings are more likely to have a high level of life satisfaction because they seek and take advantage of the novelty and unpredictability of their lives (Stephen, 2009).

A personality dimension described as **neuroticism** is characterized by anxiety, hostility, and impulsiveness. People who are neurotic experience discouragement, unhappiness, and hopelessness. For them, real-life events are screened and interpreted through a negative filter, resulting in low levels of satisfaction. In the study of Terman's gifted sample, high levels of neuroticism predicted worse physical health and lower life satisfaction (Friedman, Kern, & Reynolds, 2010).

The personality factor of **usefulness/competence** is related to **well-being** and high self-esteem in older adults. This quality is associated with informal volunteer work, higher levels of involvement with others, and a greater sense of purpose and structure in the use of time (Ranzijn, Keeves, Luszcz, & Feather, 1998). Continuing to work in later adulthood may also contribute to this sense of usefulness/competence, or perhaps those who have a high sense of usefulness/competence choose to work longer. Those older adults who take on the role of mentor for new or younger workers can enhance their sense of life satisfaction through this role to the extent that it creates opportunities to feel useful, to be involved as a valued resource, and to achieve their own career goals in this relationship (Stevens-Roseman, 2009).

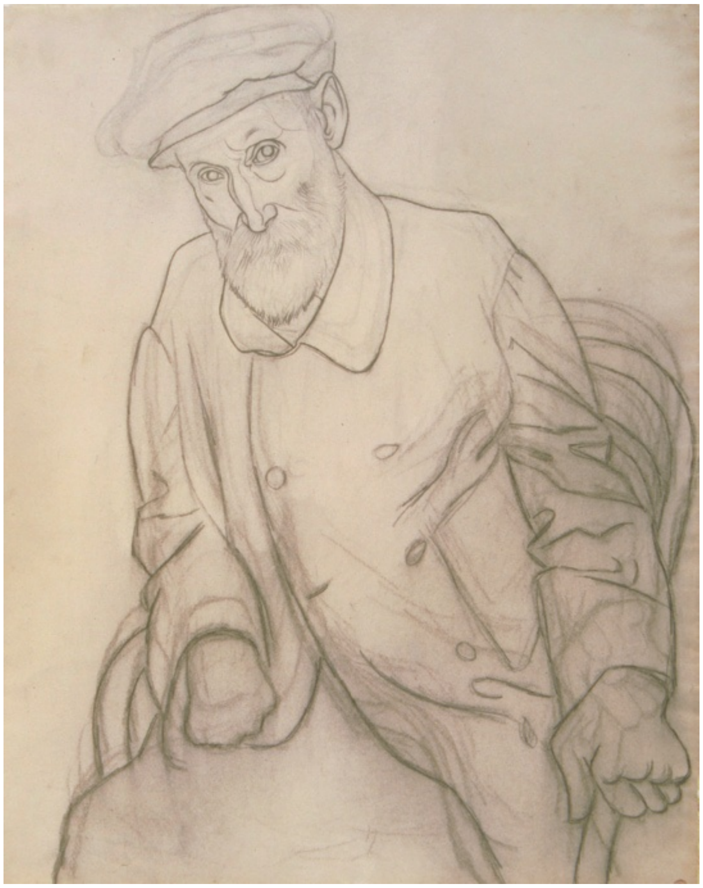
Optimism is another predictor of life satisfaction. **Optimism** is a belief that one's decisions will lead to positive consequences and that uncertain situations will turn out well. Under conditions of uncertainty and stress, adults who are optimistic have less depression, greater hopefulness, and, as a result, a greater sense of well-being (Chang & Sanna, 2001). In contrast, those who are pessimistic experience more social strain, have lower social support, and as a result, are likely to have lower life satisfaction (Luger, Cotter, & Sherman, 2009).

Along with optimism, a sense of humor has been found to predict life satisfaction. Given the many changes associated with aging, it helps to see events as amusing rather than embarrassing or demeaning. Older adults who have a good sense of humor are likely to experience life in a more playful, engaged way, even if they view life as somewhat more absurd (Ruch, Proyer, & Weber, 2010).

A **sense of control** is systematically associated with life satisfaction (McConatha, McConatha, Jackson, & Bergen, 1998). Life experiences such as engaging in physical activity, the opportunity to select one's leisure activities, or the ability to decide when to retire are all examples of factors that can improve an older adult's sense of control. A study that monitored daily activity of older adults over 2 years found that people who were able to alternate social, physical, and cognitive activities with periods of rest and relaxation had the greatest sense of happiness (Oerlemans, Bakker, & Veenhoven, 2011). Taken together these studies suggest that people who are extroverted, open to new experiences, optimistic, experience a sense of usefulness, have a good sense of humor, and feel that they are in control of events in their life will also express high levels of satisfaction.

Illness, Disability and Health

Illness and disability pose increasing challenges in later adulthood. In addition to an increase in vulnerability to acute illnesses, such as influenza, more than 80 percent of people over the age



RMN-Grand Palais/Art Resource, NY

In his later life, Renoir suffered from severe arthritis. To compensate, he tied paint brushes to his hands so he could continue to function in this highly valued domain.

of 65 have at least one chronic condition such as arthritis, hypertension, coronary heart disease, diabetes, or cancer. **Chronic illnesses** are long lasting and can be characterized by periods of intense illness followed by periods of remission or progressive decline. The most common chronic conditions in the 65 to 74 age range are arthritis, hearing impairments, heart conditions, and high blood pressure (Warshaw, 2006).

Heart disease is the leading cause of death for men and women in the United States. However, it begins about 10 years earlier for men than for women. After menopause, the risk of heart disease for women increases. Moreover, women are less likely than men to be accurately diagnosed as suffering from a heart attack, less likely to recover from it, and more likely to suffer the complications of stroke. The lifestyle factors associated with heart disease are about the same for men and women. However, men are more likely to be at risk because they do not get the physical activity they need, eat more meat and fat and less fruit and fiber than women, are less likely to go to the doctor for regular checkups, and are generally more likely to deny being sick (National Center for Health Statistics, 2013). Longitudinal studies of men consistently find that current health status and functional autonomy are significant predictors of life satisfaction (Barger, Donoho, & Wayment, 2009).

Experiencing a sense of well-being and acceptance of one's life is associated with physical health. Physical functioning and freedom from disability are included as components in the vast majority of definitions of successful aging (Depp & Jest, 2006). However, the relationship of health to life satisfaction is mediated by personality, resources, and personal goals. A chronic illness, such as arthritis, may result in a significant loss of control and reduced opportunities for physical activity or social interaction. A person who is characterized by a neurotic personality may be more discouraged and embittered by these losses than one who is optimistic or agreeable. A person whose leisure activities have focused on physical activities, such as skiing or running, may find the restrictions of arthritis more frustrating than someone whose hobbies and lifestyle are more sedentary. Subjective well-being and life satisfaction appear to be more closely tied to psychological traits, like optimism or agreeableness, and to the quality of social relationships, like having caring family and friends or being involved in community activities, than to the severity or specific nature of one's illness or disability (Jeste, Depp, & Vahia, 2010).

In a study of more than 3,000 U.S. adults, the personality traits of **conscientiousness** and neuroticism were found to be associated with mental and physical health. Adults who were more conscientious had reduced risks of health problems, whereas those who were more neurotic had increased risk. Among adults with diagnosed physical illnesses, those who were conscientious were less likely to be limited by these conditions. One explanation for this association is that the more conscientious a person is, the more likely the person will follow a recommended plan of treatment and incorporate recognized healthy behaviors into daily life (Goodwin & Friedman, 2006). Another interpretation is that those who are more neurotic are also more likely to alienate their social support system, thereby losing the important functions of social support that are associated with health and life satisfaction (Barger, Donoho, & Wayment, 2009).

It will come as no surprise that the onset of a significant disability, especially one that limits mobility or restricts the ability to work, would result in a decrease in life satisfaction. However, there is also evidence of resilience in the face of disability, more so for some than for others. In a longitudinal study of German adults, over 300 encountered a disability that led to the reduced ability to work. There was a loss in life satisfaction accompanying the disability, but over 4 years following the disability, life satisfaction began to rise. What is more, for some adults, especially those characterized by the personality quality of agreeableness, the adaptation resulted in levels of life satisfaction that returned to the same level as before the disability occurred (Boyce & Wood, 2011).

In the face of disability, the nature and quality of social relationships are especially important for promoting life satisfaction. Without support for involvement in community activities and close family and friends, older adults with disabilities are likely to become inactive and lonely, characteristics that are associated with depression (Pagan, 2015; Stancliffe, Bigby, Balandin, Wilson, & Craig, 2015). Especially for people with physical disabilities who live alone, having valued close friends can serve as a key factor in sustaining life satisfaction (Kim, Hong, & Kim, 2015).

Erikson on Accepting One's Life

Erikson's psychosocial theory places accepting one's life at the center of the psychosocial crisis of this life stage: ego integrity versus despair. The tension of this stage is created as people strive to make peace with the disappointments of the past as well as the new frailties and limitations associated with aging. Erikson et al. (1986) highlighted the importance of trust in the acceptance of one's life and the challenge of accepting support as it becomes needed.

> Maples and aspens every October bear flamboyant witness to this possibility of a final spurt of growth. Nature unfortunately has not ordained that mortals put on such a fine show. As aging continues, in fact, human bodies begin to deteriorate and physical and psychosocial capacities diminish in a seeming reversal of the course their development takes. When physical frailty demands assistance, one must accept again an appropriate dependence without the loss of trust and hope. The old, of course, are not endowed with the endearing survival skills of the infant. Old bodies are more difficult to care for, and the task itself is less satisfying to the caretaker than that of caring for infants. Such skills as elders possess have been hard won and are maintained only with determined grace. Only a lifetime of slowly developing trust is adequate to meet this situation, which so naturally elicits despair and disgust at one's own helplessness. Of how many elders could one say, "He surrendered every vestige of his old life with a sort of courteous, half humorous gentleness"? (p. 327)

The U-Shaped Curve of Well-Being

The general sense of subjective well-being can be defined as a combination of beliefs and feelings about whether one is leading a desirable, rewarding life (Diener, 2012). Studies across cultures find that certain factors including social support, trust, and a sense of mastery or control predict well-being. What is more surprising is that many studies find a U-shaped relationship of age and well-being (see FIGURE 13.2 ▶). The sense of well-being decreases to a low point in the late 40s and early 50s and then increases steadily with advanced age (Blanchflower & Oswald, 2007; Stone, Schwartz, Broderick, & Deaton, 2010). Controlling for income, employment status, and having children, the U-shaped pattern is still observed.

In an analysis of well-being across 46 countries, the U-shaped curve held up in 44. In this study, well-being was measured using the Cantril ladder question: "Please imagine a ladder, with steps numbered from 0 at the bottom to 10 at the top. On which step of the ladder would you say you personally feel you stand at this time?" The data came from the Gallup World Poll for the years 2005–2014, with an average of 9,000 observations per country. The bottom of the well-being curve occurred in the age range 40 to 60, depending on the country. Two additional observations emerged from this cross-national study: (1) The curve begins to ascend at a younger age in countries where the national level of well-being is higher, and (2) within countries, the curve ascends at a younger age for individuals who are more satisfied with life as compared to those who are less satisfied overall. The implication is that even though they will experience a decline in life satisfaction during a period of middle adulthood, people who are satisfied with their lives and who live in places where most people are satisfied have more years of middle and later adulthood when they experience satisfaction with life (Graham & Pozuelo, 2016).

Four explanations may account for this U-shaped trend in life satisfaction:

- Happiness is associated with health. Since health and happiness are both associated with longevity, it is possible that those who are unhappy with their lives also die younger. Thus, the older sample includes more people who have been happier with their lives all along whereas more of the unhappy people have died.
- Older people are less angry, less likely to engage in conflicts, and better able to find solutions to conflicts, resulting in lower experiences of stress.
- Older people are more likely to focus on what matters in the present and not worry as much about what the future holds.
- Older people may give up certain kinds of strivings and accept the life they have.

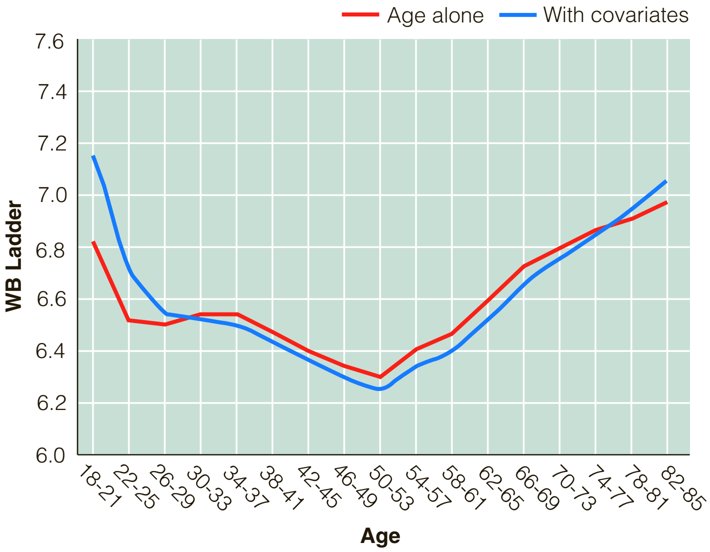


FIGURE 13.2 ▶ THE U-SHAPED CURVE OF WELL-BEING

FURTHER REFLECTION: *Explain how people might modify their goals in later adulthood in order to optimize life satisfaction. Give an example from your own experience or from the life of someone you know that illustrates this idea.*

Promoting Intellectual Vigor

OBJECTIVE 2 Define intellectual vigor, and describe factors that promote it in later life. Evaluate evidence about the interaction of heredity and environment on intelligence in later life.

Over the life span, adaptation and survival depend on a person's ability to meet the demands of their environment. Problem solving, which begins in infancy at the sensory and motor levels, becomes increasingly flexible, abstract, and adapted to the context and situation, over the life course. **Memory**, reasoning, information processing, problem-solving abilities, and mental rigidity or fluidity all influence an adult's **intellectual vigor**, the capacity to introspect, select meaningful goals, manage changing resources, and plan for the future. These intellectual capacities also influence the adult's ability to remain involved in productive work, advise and guide others, and invent new solutions to the problems of daily life. The person's capacity to cope with the challenges of later adulthood, and thereby preserve a high level of life satisfaction, depends on the ability to promote and sustain intellectual vigor. It is not surprising to know that there is a link between well-being and cognitive functioning. Among older adults, well-being is associated with better performance on tests of cognitive functioning. What is more, people who perform better on certain tests of cognitive functioning are likely to be better able to handle tasks of daily life, engage in challenging problem-solving, and as a result, experience more positive mood and higher quality of life (Allerhand, Gale, & Deary, 2014).

In the following section, we review problems associated with the study of intelligence and aging that make it difficult to make broad generalizations. Specific topics are then discussed including neuroplasticity in later life, memory, problem solving in loosely defined situations, and an overview of age-related changes in various mental abilities. The focus then shifts to an analysis of the impact of heredity and environment on intelligence and factors that help to sustain high levels of intellectual functioning in later life.

Problems in Defining and Studying Intelligence in Later Adulthood

The primary goals in the study of development are to describe and explain patterns of change and continuity over time. Four problems arise in evaluating the research on intelligence in later life (Stuart-Hamilton, 1996). First, one must differentiate between **age differences** and **age changes**. Suppose that in a cross-sectional study conducted in 2000, 70-year-olds performed less well on tests of flexible problem solving than 40-year-olds. The difference may be clear, but it may not be a result of age alone. The 70-year-olds would have been born in 1930, and the 40-year-olds in 1960. Differences in performance may be a product of different educational opportunities, varying experiences with standardized tests, or other cohort-related factors. Educational opportunities increased markedly during the 20th century so that younger cohorts are much more likely to have benefited from formal schooling at both the high school and college levels (U.S. Bureau of the Census, 2000). For example, only 10 percent of people ages 65 to 74 in 2000 had completed a bachelor's degree, whereas 18 percent of adults ages 35 to 44 had attained this level of education. In the older cohort, 26 percent had not graduated from high school, compared to 11 percent in the younger cohort. Advanced education is associated with greater reflectiveness, flexibility, and relativistic thinking (King & Kitchener, 1994; Labouvie-Vief & Diehl, 2000).

In cross-sectional studies of cognitive functioning, historical factors may be confounded with developmental or aging factors that contribute to observed differences in performance. In longitudinal studies that follow change over time, if only one cohort is sampled, it is impossible to tell whether changes from one period to the next are products of age and development or a result of fluctuations in resources and challenges faced by that particular generation.

A second problem is the *definition of abilities*. Cognitive functioning is a broad term that encompasses such varied abilities as vocabulary, problem solving, and short-term memory. It is possible that the pattern of change in abilities with age depends on which abilities are tested. Some abilities are frequently used and have been developed to a high level of efficiency. For example, an architect is more likely to retain abilities in spatial relations and reasoning than is someone whose work is not intimately connected with the construction and organization of spatial dimensions.

A third related problem is the *relevance of the tasks* used to measure adult cognitive functioning. The definition of intelligence that is used in the design and application of most intelligence tests refers to capacities that are predictive of school-related success. The criteria for assessing adult intelligence are necessarily more varied than the ability to succeed in a school curriculum. Furthermore, motivational factors come into play in the measurement of intelligence. This raises the distinction between *ability* and *performance*. If a test is perceived as irrelevant or unimportant, an adult may not give much effort to performing well.

Finally, *factors associated with health* are intertwined with the functioning of older adults, although they are often not directly measured. A number of age-related diseases impact an individual's ability to learn and retain new information. However, the boundaries between what might be considered normal cognitive changes associated with age and disease-related changes are not easy to detect, especially in the early stages of an illness (Albert, 2002). In a longitudinal study of intelligence, Riegel and Riegel (1972) found clear declines in performance among participants who died before the next testing period. Vocabulary skills, which normally remain high or continue to show increases with age, are especially likely to decline in older individuals who will die within the coming few years. Adults who are in the early stages of dementia but have not yet been diagnosed as suffering from the disease are often included in samples described as normal or normative. This inclusion lowers the mean of the total group and overestimates the negative association of age and intelligence (Sliwinski, Hofer, Hall, Buschke, & Lipton, 2003). At each older age, the inclusion of adults who are in an early phase of a progressive illness lowers the average performance of the group as a whole.

Neuroplasticity and Aging

Aging is normally accompanied by some decline in cognitive abilities, especially abilities that rely heavily on processing speed, working memory, and long-term memory. Cognitive capacities are impacted by a variety of changes in the brain including shrinking volume of brain structures, deterioration of white matter, and amyloid plaque deposits in the arteries and between nerve cells as well as tau tangles in the brain cells (Park & Bischof, 2013). The decline in cognitive ability can be minimal or serious enough to interfere with a person's ability to live independently. In chapter 14 we discuss Alzheimer's disease, a form of dementia that results in the extreme deterioration of cognitive capacities.

Despite these patterns of possible loss in cognitive functioning, the aging brain has continuing capacity for plasticity. A variety of mentally stimulating and challenging experiences that are carried out over time can result in increases in the number of synapses, the actual thickness or volume of brain structures, the development of new connections among neural networks, and the activation of brain areas related to new skills and abilities. The most striking evidence of this plasticity comes from experiences with patients who have had a stroke, resulting in permanent damage to a specific region of the brain. With many hours of training to develop specific skills, brain areas that are not normally involved can be recruited to take over for the damaged areas. For healthy adults, the nature of plasticity may not be as dramatic. However, there is evidence that when older adults face new tasks that place repeated demands on basic capacities like speed of response, memory, and reasoning, new neural networks may be formed, and new regions of the brain are activated.

Reserve capacity has been theorized to protect cognitive functioning in healthy adults. **Reserve capacity** refers to the idea that with age, older adults are able to maintain a high level of cognitive ability by drawing on bilateral frontal regions to accomplish tasks of working memory and episodic encoding. They use additional neural resources to achieve the same level of competence that was previously accomplished with less neural activation. Certain life experiences, especially education (including early childhood education), high levels of literacy, engagement in cognitively and socially stimulating activities, a healthy diet, and physical activity are all thought to contribute to "brain health" and the maintenance of neural reserve that supports plasticity (Baltes & Baltes, 1990; Erikson, Gildengers, & Butters, 2013; Max Planck Institute for Human Development and Stanford Center on Longevity, 2014; McDonough, Haber, Bischof, & Park, 2015).

Memory

The exact nature of changes in memory with age is a topic of active and ongoing research (Hertzog & Shing, 2011; Johnson, 2003; Lustig & Lin, 2016). A common model breaks memory into three forms: the sensory register, working member (including short-term memory), and long-term memory; and three functions: encoding, storage, and retrieval. In this model, the **sensory register** is the neurological processing activity that is required to take in visual, auditory, tactile, and olfactory information. **Encoding**, which involves attending to information, perceiving it, and catching the gist or drift of the information, begins with the sensory register. **Speed of processing** which is most closely linked to the sensory register, can be slowed as a result of illness. Illness does not seem to affect higher order aspects of memory, particularly the recall of past life events (Rosnick et al., 2004).

Once information is encoded, it has to be stored. **Working memory** has been described as comprising several different capacities (Cowan, 2008). It includes, **short-term memory**, which is the capacity to encode and store five to nine bits of information in the span of a few seconds to a minute or two. This is the scratch pad of memory that is used when someone tells you a telephone number or gives you an address. Short term memory has a limited capacity and fades rapidly.

Working memory uses attention and other executive functions to manipulate and manage information in short term memory, especially when cognitive tasks are involved. For example, you use working memory when you are looking for airline flights online. You may scan quickly through the schedule of flights to see which ones have the best departure times, number of stops, and cost. You are very briefly comparing bits of information, not intending to recall all of them, but hoping to spot one or two that will work for you.

Long-term memory is a complex network of information, concepts, and schemes related by associations, knowledge, and use. It is the storehouse of a lifetime of information. Remembering something for more than a few minutes involves moving the information from short-term to long-term memory, storing it in relation to other associated knowledge, and being able to recognize, retrieve, or reconstruct it at a later time (Hoyer & Verhaeghen, 2006).

The memory functions most relevant to understanding cognitive ability in aging have to do with the ability to transfer and store information from short-term to long-term memory and then retrieve it. Studies that compare the short-term memory abilities of older and younger adults find that age is not associated directly with the capacity of short-term memory, but with the ability to transfer newly learned information to long-term memory and then retrieve it on demand. Older adults are just as effective as younger adults in recognizing information that was learned in the past, but they have difficulty summoning up a specific name or number when they want to find it (Hertzog, Fulton, Mandviwala, & Dunlosky, 2013; Rowe & Kahn, 1998).

Furthermore, older adults find that their memory functions are especially likely to be disrupted under conditions in which information is presented rapidly and contextual cues are absent. Older adults rely on meaning to store and retrieve new information. With each passing year of life, there is more to remember. We do not really know the limits of the storage capacity of long-term memory.

Studies of memory focus on different kinds of tasks, each with its own trajectory of growth and decline. **Semantic memory** focuses on basic knowledge, such as recalling the meaning of words like *vegetable*, *democracy*, or *insect*. Once learned, semantic memory seems very resistant to loss. People continue to grow in the accumulation of new ideas and information over adulthood.

Episodic memory focuses on specific situations and data. Measures of episodic memory may ask people to recall words from a list or remember what they had for breakfast 3 days ago. In general, episodic memory declines modestly with age. With age, so many daily events and bits of information are encountered that unless the events have some particular importance, they may not be encoded, or may become difficult to retrieve in the accumulated network of memories. There are exceptions to this decline, however, depending on the type of task involved (Zelinski, 2009).

A third type of memory task is called **prospective memory**. This is memory about events or actions taking place in the future. An example would be remembering to take pills at 4 p.m. or to call a spouse when arriving at a hotel after traveling on a business trip. This type of memory task requires recalling that something needs to happen at a future time or under some future condition and also remembering specifically what needs to be done. Older adults do not do as well as young adults on prospective memory tasks in laboratory conditions. However, in naturalistic studies, the older adults do better than the young adults (Henry, MacLeod, Phillips, & Crawford, 2004). Prospective memory is a critical component of adaptive coping, and older adults use a variety of strategies to help stay attuned to their functional future.

Research using the narrative method suggests that people construct memories that make sense of their past. They tell a story about the past that puts events in a chronological sequence, highlighting events that, in retrospect, are important achievements or turning points. For example, in one study, participants were asked to provide a narrative about a time when they said, thought, or did something wise. Adolescents as well as younger and older adults were all able to retell experiences where wisdom helped them to turn a negative experience into something positive. Adults were also able to describe how the wisdom experience helped shape their outlook or life philosophy (Bluck & Gluck, 2004). Memory may be used in a new way in later adulthood in order to resolve the conflict of integrity versus despair. Memory is used to recall and evaluate certain salient life events until the role of these events can be integrated into a meaningful sense of one's purpose. This process may interfere with an adult's ability to attend to current minutiae or to rehearse and recall new information.

There is wide variability in people's memory skills (Zelinski & Lewis, 2003). Some people pay great attention to details and are more able to recall them. Others ignore many details and are not able to retrieve them. A salesman or politician may have a knack for remembering the names of friends, acquaintances, and family members. A historian may have a memory for historical events and personalities. A police detective may pay great attention to the details of the physical environment from specific cases. As the demands of work and family life accumulate, people adapt by focusing attention on the details and events that are most salient for their success. Over time, the differences in people's approaches to what they have learned, recalled, and found useful in coping with life shape the context for whether and how new information is encoded and retrieved.

In addition to actual declines in some kinds of memory performance, older adults complain of memory problems. Anxiety and frustration over memory loss nag many, even those older adults whose memory performance has not dramatically declined. However, memory complaints may reflect the person's accurate subjective assessment of a slowing in the retrieval process, or a decline in their episodic memory (Price, Hertzog, & Dunlosky, 2010). A loss of memory self-efficacy can become a hindrance to effective performance on memory tasks. Low self-efficacy regarding one's memory may lead to an avoidance of tasks that require episodic memory, such as playing certain types of games or attending social events where one is expected to recall the names of new associates.

In hopes of understanding the degree of resilience or plasticity available in the memory capacity of older adults, various training studies have been performed. Training strategies have been shown to improve the memory of older adults. However, when younger and older adults are given the same training, the younger adults benefit significantly more and show greater improvement in their memory skills than the older adults. In one study, training was found to improve performance in memory, attention, processing speed, and word recall, but after 3 months of no training, the group receiving training was no different from the control group. Thus, training was viewed as having a short term impact rather than a long term benefit (Singer, Lindenberger, & Baltes, 2003; Zelinski et al., 2011).

Solving Loosely Defined Problems

Research based on the standard Piagetian tasks has been criticized for its lack of relevance and familiarity to older participants. These tasks are dominated by the role of pure logic, disconnected from the situation. They emphasize problems that have a scientific rather than a pragmatic focus. Although the solution to most formal operational problems requires the manipulation of multiple variables, there is typically only one correct solution. In adult life, most problems involve multiple dimensions with changing or poorly defined variables and more than one solution. For example, given my limited resources, should I buy more life insurance, put cash in a certificate of deposit, or invest in the stock and bond market to best protect my family's financial future?

As a result of these limitations or criticisms of formal operational reasoning, scholars have formulated a view of **postformal thought**, which has been characterized in the following ways (Commons & Richards, 2003; Labouvie-Vief, 1992; Sinnott & Cavanaugh, 1991).

- A greater reliance on reflection on self, emotions, values, and the specific situation in addressing a problem
- A willingness to shift gears or take a different approach depending on the specific problem
- An ability to draw on personal knowledge to find pragmatic solutions
- An awareness of the contradictions in life and a willingness to try to include conflicting or contradictory thoughts, emotions, and experiences in finding a solution
- A flexible integration of cognition and emotion so that solutions are adaptive, reality oriented, and emotionally satisfying
- An enthusiasm for seeking new questions, finding new problems, and new frameworks for understanding experience

Different types of problems require different strategies. When a problem has clear parameters and needs a single solution, concrete or formal operations may work. However, when a problem is loosely defined, value laden, ambiguous, or involves many interpersonal implications, a more flexible approach may be required. Given the complexity of adult life, adaptive problem solving requires flexibility, differentiation of positive and negative aspects of a single alternative, and the ability to consider the implications of a course of action. When older adults face a loosely defined problem, they tend to consider multiple aspects of the situation. Their solution is altered depending on the larger overall goal they are striving to achieve (Berg & Strough, 2011).

Increasingly, problem solving becomes a social task, whereby several people or groups of people work together to arrive at solutions. Older adults tend to be sensitive to the emotional impact of their solution, especially when the problem is embedded in a social situation. Older adults are likely to strive for a solution that maintains harmony and avoids conflict. They benefit from collaboration with a close or trusted colleague or partner in solving complex problems, drawing on the collective experience of their partner in identifying alternative strategies. Collaborative problem solving includes the ability to balance the interpersonal and analytical aspects of the work. Because members of groups are vulnerable to pressures toward conformity or groupthink, it is important for individuals to retain their capacity to differentiate or distance themselves from the group in order to examine the group's product in a more objective light. At the same time, when trusted and valued colleagues work together, the product may become a more creative, innovative solution than any single individual may have been able to produce alone (Martin & Wight, 2008).

Patterns of Change in Different Mental Abilities

How readily can older adults improve their skills or learn new skills? This question seems to produce two different kinds of answers (Kühn & Lindenberger, 2016). One line of research finds evidence of DNA damage in the human brain with reduced capacity for repair beginning after about age 40. Damage of this kind has negative consequences for plasticity leading to declines

Diplomacy is an example of advanced problem solving that requires interpersonal skills, collaboration, and an awareness of the rules and conditions impacting the political constraints on the partners.

in learning and memory. Certain brain areas are more vulnerable to the accumulated stressors of aging than others, and certain individuals are more vulnerable to the neurological diseases of aging than others (Erraji-Benchekroun et al., 2005; Lu et al., 2004; Mattson & Magnus, 2006).

In contrast, other researchers find that among people in their 60s and 70s, continuing improvement in performance is possible through training and practice. According to this view, much of the decline in cognitive performance is a result of limited educational opportunities and disuse. Following training, improvement has been observed in tasks involving memory, reasoning, perceptual-motor speed, and visual attention, as well as specific areas of expertise (Krampe & Charness, 2006; Yang, Krampe, & Baltes, 2006). In one longitudinal study, cognitive interventions resulted in a long-term benefit lasting from 7 to 14 years after the training (Schaie & Willis, 2010). One possible way to reconcile these opposing observations is to consider how different types of mental abilities might change with age.

John Horn (1979) proposed that the course of mental abilities across the life span is not uniform. Some areas are strengthened, and others decline. Horn suggested differentiating **crystallized intelligence** (*Gc*) and **fluid intelligence** (*Gf*). *Gc* is the ability to bring knowledge accumulated through past learning into play in appropriate situations. *Gf* is the ability to impose organization on information and generate new hypotheses. Both kinds of intelligence are required for optimal human functioning.

Gc and *Gf* can be identified as integrated structures in both early and later adulthood (McArdle, Ferrer-Caja, Hamagami, & Woodcock, 2002). However, Horn argued that these two kinds of thinking draw on different neurological and experiential sources. *Gc* reflects the consequences of life experiences within a society. Socialization in the family; exposure to the media; and participation in school, work, and community settings all emphasize the use and improvement of *Gc*. *Gc* increases with age, experience, and physical maturation, and remains at a high level of functioning throughout adulthood.

Gf is characteristic of what is meant by someone having common sense. Finding a general relationship and applying it without having been schooled in that problem-solving area is an example of *Gf*, as is being able to approach new problems logically, systematically, and quickly. Horn hypothesized that *Gf* depends more on the specific number of neurons available for its functioning than does *Gc*. Thus, neurological loss would be more damaging to *Gf* than to *Gc*. Neural efficiency, often recognized through changes in sensory functioning and speed of response, is closely related to fluid intelligence and shows an age-related decline, independent of disease (Baltes & Lindenberger, 1997). However, the extent of this decline may be related to the domain in which it is studied. For example, one study focused on men who had different levels of expertise in playing the game of Go. Measures of reasoning, memory, and cognitive speed were developed to apply specifically to that game. Older players generally showed the expected decline in deductive reasoning and cognitive speed. However, for those older men who were very expert players, no decline was observed (Masunaga & Horn, 2000). The implication is that in areas where there is highly developed expertise, aging is not necessarily accompanied by declines in either *Gf* or *Gc*.

In an analysis of the pattern of cognitive abilities across the life span, Tucker-Drob (2009) gathered data from a nationally representative sample of over 6,000 individuals from ages 4 to 101. He compared high and low scoring individuals at different ages to address two basic questions: (1) How do various abilities change with age? (2) Do abilities cluster together (e.g., people who are good at visual-spatial thinking are also good at short-term memory), or is there differentiation among abilities with age (people can be very good in one area, and average or not so strong in another)? Seven areas of cognitive ability were measured: comprehension knowledge (similar to *Gc*), fluid reasoning (*Gf*), visual-spatial thinking (e.g., identifying the pieces needed to complete a pattern), processing speed (e.g., quickly identifying two identical numbers in a row of numbers), short-term memory (e.g., repeating a list of unrelated words), long-term retrieval (e.g., naming as many examples as possible from a specific category of places or objects), and auditory processing (e.g., identifying a word when it is presented against a competing background of distracting sounds).

As illustrated in FIGURE 13.3 ▶, all the abilities with the exception of *Gc* increased in childhood and adolescence, peaked in later adolescence and early adulthood, and then declined through adulthood and aging. In contrast, crystallized intelligence continued to increase throughout adulthood, until about age 60, and then declined slightly into later life. Among those of higher general intelligence, there was less commonality in the scores across the various cognitive abilities suggesting that with greater intelligence comes a greater capacity to express certain abilities to a

Legend: *Gc* = comprehension knowledge; *Gv* = visual spatial thinking; *Gf* = fluid reasoning; *Gs* = processing speed; *Gsm* = short term memory; *Glr* = long-term retrieval; *Ga* = auditory processing.

uniquely high level. Over the life span, the abilities were more differentiated; that is, people in middle adulthood and later life showed more variability in their cognitive capacities than did younger children and adolescents.

The Interaction of Heredity and Environment on Mental Functioning

For years, it was assumed that the environment played an increasingly major role in intellectual functioning over time. The accumulation of life experiences, education, and socialization were expected to introduce new bases of knowledge and problem-solving structures. Recent work suggests that the construct of the norm of reaction, introduced in chapter 4 (The Period of Pregnancy and Prenatal Development), provides a more appropriate framework for understanding intelligence in adulthood. Genetic factors, early childhood family environment, and contemporary work and family environments all contribute to adult cognitive functioning (Reynolds & Finkel, 2016).

Research on identical and fraternal twins who were 80 years old or older found that the heritability of general cognitive ability was about 60 percent (McClearn et al., 1997). In other words, genetic factors substantially contribute to the stability of cognitive capacities over the life span. Hereditary factors related to health also impact cognitive functioning. For example, genetic factors that contribute to longevity are associated with resistance to disease and greater vitality in late life. Likewise, hereditary factors associated with diseases that have a late-life onset such as Parkinson's or Alzheimer's disease contribute to changes in cognitive functioning with age (Wilcox, Wilcox, Hsueh, & Suzuki, 2006).

Evidence also supports the increasing role of the environment on cognitive functioning in late life. Long-term exposure to environmental toxins, poor nutrition, or social isolation can impair optimal cognitive abilities. The stimulating or stifling nature of the environment—including access to social support, the quality of health care, exposure to disease, and opportunities for continuing involvement in challenging work—transforms the genotype into an observed phenotype (Baird & Bergeman, 2011; Gottesman, 1997; Shanahan & Hofer, 2005).

The noted learning theorist B. F. Skinner (1983) described some possible environmental qualities that fail to reinforce systematic thinking or new ideas in aging people. Many people who live alone, for example, lack the diversity of social interaction that produces cognitive discrepancy and new concepts. Older people may be reinforced for talking about the past. Their recollections of early memories are interesting to students and younger colleagues. However, preoccupation with these reminiscences does not encourage thinking in new directions.

Skinner claimed that one is more likely to repeat oneself as one ages. It may be important for older adults to move into new areas of work in order to prevent the repetition of old ideas. Skinner believed that it is possible to analyze how the quality of one's thinking is influenced by the circumstances of aging and to identify interventions that will prevent the deterioration of cognitive abilities. These interventions include attempts to be sensitive to the signs of fatigue, planning for regular opportunities for stimulating verbal interactions with others, making careful outlines of written work to avoid distraction, and acting on ideas as they come to one's mind rather than counting on remembering them later.

In summary, cognitive functioning in later adulthood is multidimensional, with substantial differences among individuals as well as differences among cognitive domains within the same person (McArdle et al., 2002). Within these domains, many complex networks of information, strategies, and frameworks of meaning are elaborated that may result in high-level, flexible functioning. The overall level of functioning is subject to environmental influences that promote particular specialization and cognitive organization based on the demands of the situation, the stresses and challenges of daily life, and the opportunities for mastery in particular areas of competence. At the same time, certain aspects of the processing base that are dependent on neural functioning may decline with age. This decline, however, is not always great, and capacities described as elements of fluid intelligence, such as speed of response, inductive reasoning, and spatial orientation, can benefit from targeted interventions (Saczynski, Willis, & Schaie, 2002; Yu, Ryan, Schaie, Willis, & Kolanowski, 2009). As the baby boomers have entered the stage of later adulthood, their desire to maintain intellectual vigor and to hold at bay the risks of cognitive decline have made them a ready market for a burgeoning computer-based brain game industry. The **Applying Theory and Research** box reviews the opinions of scientists regarding the effectiveness of these games for enhancing intelligence among older adults.

On the basis of extensive longitudinal research, the following factors have been identified as effective for retaining a high level of cognitive functioning in later adulthood:

1. Absence of cardiovascular and other chronic diseases
2. Favorable environment linked to high socioeconomic status
3. Involvement in a complex and intellectually stimulating environment

APPLYING THEORY AND RESEARCH TO LIFE

Can Computer "Brain Games" Prevent or Reverse Cognitive Decline Associated with Aging?

Two seemingly opposing processes are at work in relation to cognition and aging. First, there is evidence of decline in certain capacities, especially those related to fluid intelligence, including speed of processing, working memory, auditory processing, and short-term memory. Second, there is evidence of plasticity with aging, especially when adults engage in activities that place a repeated and significant demand on their cognitive abilities. In the face of these facts, a growing industry has emerged to produce and market computer-based cognitive training software, sometimes called "brain games." Advertisers often claim that playing the games will increase alertness, allow one to learn faster, increase intelligence, and improve memory. What does the scientific community of cognitive psychologists and neuroscientists make of these claims? Does the research evidence support these claims?

The Stanford Center on Longevity and the Max Planck Institute on Human Development invited a large group of scientists to evaluate the existing research and offer a consensus report to the public. Some studies show that practicing certain skills results in improvement, including improvement in other cognitive tasks. Some studies find long lasting improvements, whereas others find that improvements fade in a few months. When there are improvements in performance, it is difficult to determine whether the gains are due to changes in strategies the player uses to manage the challenges of the game or to changes in brain plasticity at the neural level, such as increases in the number of synapses, activation of neural regions, or changes in the connections among neural networks (Park & Bischof, 2013).

Overall, the consensus is that the existing scientific evidence does not support claims that playing brain games improves "underlying broad cognitive abilities or that it enables one to better navigate a complex realm of everyday life" (Stanford Center on Longevity and the Max Planck Institute on Human Development, 2014). Claims that brain games can reduce or reverse the effects of cognitive decline associated with aging are not supported by scientific evidence. Their report provides the following recommendations/conclusions:

1. No studies have demonstrated that playing computer-based games cures or prevents Alzheimer's disease or other forms of dementia.
2. Before the benefits of these games can be accepted, research findings need to be replicated in different laboratories with different investigators. Studies need to demonstrate advantages of playing the computer games in comparison to appropriate control groups that do not play the games but are treated in a similar way.
3. The limited evidence does not support the transfer of gains in a particular skill, even if the gains endure, to other more global cognitive abilities or capacities for functioning in daily life.
4. Researchers need to consider the relative benefits of playing computer brain games against the benefits of other activities a person might be doing. Currently the known benefits of engaging in socially complex, physically and intellectually challenging activities on brain health and plasticity have not been systematically compared to the benefits of spending a similar amount of time playing brain games.
5. The known benefits of physical exercise for general health and brain health include increased blood flow to the brain and associated improvements in attention, reasoning, some aspects of memory, and well-being. The cognitive benefits of sitting in front of the computer playing brain games versus engaging in physical activity that increases blood flow have not been assessed.

Critical Thinking Questions

1. How would you design a study to test the hypothesis that playing "brain games" has a benefit for neural plasticity above and beyond improvements in strategy?
2. Which cognitive abilities do you think might benefit most from playing computer brain games? Why?
3. Talk to some people in later adulthood about their concerns regarding cognitive decline. Analyze how brain games are marketed to appeal to people with these concerns.
4. Do you play brain games? What do you like about them? What makes them fun? If you have never played them, try one or two just for the experience. What is your assessment? Would you pay money to keep playing? Why or why not?

4. A strong sense of control over one's work
5. Flexible personality style at midlife
6. High cognitive functioning of spouse
7. Maintenance of a high level of perceptual processing speed
8. Rating oneself as being satisfied with life accomplishments in midlife

This list illustrates the interplay of the biological, psychological, and social systems that contribute to cognitive functioning in the later years (Schaie, 1994; Schaie & Willis, 2010). Retaining one's intellectual vigor and problem-solving abilities is closely linked to the ability to cope with the inevitable role transitions that occur in later life.

FURTHER REFLECTION: Summarize the aspects of intellectual functioning that are most vulnerable to the effects of aging. What are some strategies that individuals can use to preserve and/or promote intellectual vigor?

Explain some ways that the social environment, including immediate family, friends, and community resources, may influence cognitive functioning in later life.

Redirecting Energy to New Roles and Activities

OBJECTIVE 3 Explain the process of redirecting energy to new roles and activities, with special focus on role gain, such as grandparenthood; role loss, such as widowhood; and new opportunities for leisure.

Role transition, role gain, and role loss occur in each life stage. In later adulthood, however, a convergence of role transitions is likely to lead to a revision of major life functions and a reformulation of one's lifestyle. Roles are lost through widowhood, retirement, and the death of friends. At the same time, new roles, such as grandparent, senior adviser, or community leader, require the formation of new patterns of behavior and relationships. In the following sections, we focus on three specific role transitions: grandparenthood, widowhood, and leisure roles.

Grandparenthood

Grandparenthood provides opportunities for psychosocial growth, both for individuals and for grandparent couples (Taubman-Ben-Ari, Findler, Ben Shlomo, 2013). Becoming a grandmother or grandfather brings a psychological transformation as well as a change in the family system. With the birth of a first grandchild, an adult may begin to reflect on one's own life phases of childhood, parenthood, and **grandparenthood**, revisiting earlier personal and interpersonal themes, and possibly revising earlier understandings of the parent–child relationship. Depending on one's level of engagement in the grandparent role, grandparenthood may require a renewal of parenting skills that have been stored away along with the bottles, bibs, and potty chairs. Grandparents begin to rekindle their acquaintance with the delights of childhood, including diapering the baby, telling fairy tales, taking trips to the zoo, or having the pleasure of small helping hands with baking, gardening, or carpentry. A person's parenting skills, patience, and knowledge come into play in a new configuration and may be more in demand in the grandparent role than they were in the parent role.

Grandparenting Styles. Grandparenthood involves a three-generational family system. The average age for becoming a grandparent is in the decade of the 50s, resulting in the potential of a 20- to 30-year relationship with one's grandchildren. The enactment of the grandparent role depends on the timing of entry into this role and on the outlook or interest of each generation in having interactions and access to one another. The quality of the grandparent–grandchild relationship is negotiated through the adult child and is likely to change as the grandchildren mature (Giarrusso, Silverstein, & Bengston, 1996; Smith & Drew, 2002).

Certain common factors appear to predict feelings of closeness between grandchildren and their grandparents. These include frequent contact, grandparents' educational level, younger age of the grandparent, and general health. Maternal grandmothers tend to be more involved in their grandchildren's lives than other grandparents (Danielsbacka & Tanskanen, 2012; Hakoyama & MaloneBeach, 2013).

People differ in the way they enact the grandparent role. In one of the first empirical studies of grandparenthood, Neugarten and Weinstein (1964) interviewed grandparents in 70 middle-class families. Five grandparenting styles were identified, each expressing a distinct interpretation of the role:

1. *Formal*. Grandparents were interested in the grandchildren but careful not to become involved in parenting them other than by occasional babysitting.
2. *Fun seeker*. Grandparents had informal, playful interactions with the grandchildren, enjoying mutually self-indulgent fun with them.
3. *Surrogate parent*. This style was especially likely for grandmothers who assumed major child care responsibilities when the mother worked outside the home.
4. *Reservoir of family wisdom*. This style was an authoritarian relationship in which a grandparent, usually the grandfather, dispensed skills and resources. Parents as well as grandchildren were subordinate to this older authority figure.
5. *Distant figure*. Grandparents appeared on birthdays and holidays but generally had little contact with the grandchildren.

More than 35 years later, Bengston (2001) offered a revised picture of the nature of multigenerational family bonds based on the Longitudinal Study of Generations (LSOG), begun in 1971, and continuing with data collection every 3 years. This study of more than 2,000 members of three-generational families, provided the assessment of relationship characteristics between parents and their adult children, adult children and their children, and grandparents and grandchildren. The study found that the way a person enacts the grandparent role is not only a product of a personal definition of the role, but also a result of how the interconnected family members permit and support intergenerational interactions.

The LSOG identified five aspects of **intergenerational solidarity**—a construct that reflects closeness and commitment within the parent–child and grandparent–grandchild relationships.

1. *Affectional solidarity*: Feelings of affection and emotional closeness
2. *Associational solidarity*: Type and frequency of contact
3. *Consensual solidarity*: Agreement in opinions and expectations
4. *Functional solidarity*: Giving and receiving emotional and instrumental support
5. *Structural solidarity*: Geographic proximity that would allow for interaction

Based on these dimensions, five intergenerational family types were identified, which closely resemble the grandparenting roles characterized by Neugarten and Weinstein. The *tight-knit* families were emotionally close, lived near one another, interacted often, and both gave and received help. The *sociable* families were emotionally close and had frequent contact but did not offer much functional help. The *intimate but distant* families had high levels of agreement and felt emotionally close but did not interact often, lived far apart, and offered little functional help. The *obligatory* families lived near one another and had frequent contact but were not emotionally close and did not share much in the way of common opinions or expectations. Finally, the *detached* families had low levels of all measures of solidarity.

Looking at the adult children's views of their parents, the sample was divided rather evenly across the five groups. Tight-knit and sociable families were each about 25 percent of the sample, obligatory and intimate but distant families were each about 16 percent, and detached families were about 17 percent. When ethnic groups were compared, European Americans were more likely than African Americans or Hispanic Americans to describe their relationship with their mother as obligatory or detached. Cultural dimensions including the emphasis on filial obligation, immigration or acculturation status, and the symbolic meaning of linkages to one's ancestry all influence the emphasis that various cultures place on the grandparent role (Ikels, 1998). Some cultural differences observed in the enactment of the grandparent role are described in the **Human Development and Diversity** box Intergenerational Relationships in Various Ethnic Groups.

Two important ideas emerge from these descriptions. First, contemporary U.S. families are characterized by a variety of intergenerational relationships. No single type is normative. Second, about two thirds of these relationships can be characterized as showing high levels of affectional and consensual solidarity. This has been observed in repeated measurements between 1971 and 1997. Thus, despite many changes in family characteristics, including decreased family size, increased involvement of mothers in the labor force, parental divorce, and increasing educational attainment of the parent generation, sentiments of intergenerational closeness are strong. This implies an important stabilizing role for the grandparent generation—a role that may become increasingly important for the large number of children growing up in single-parent and dual-earner parent families.

The Meaning of the Grandparent Role. Grandparenthood has a variety of personal meanings that contribute to the grandparent's overall sense of purpose and worth (Gattai & Musatti, 1999; Kivnick, 1988; Scraton & Holland, 2006). Grandchildren symbolize an extension of personal influence that will most assuredly persist well beyond the grandparent's death. To this extent, grandchildren may help older adults feel more comfortable about their own death. Grandchildren offer concrete evidence that some thread of their lives will persist into the future, giving a dimension of immortality to themselves and the family ancestry that they represent.

Active grandparenting may promote a process of life review, stimulating a revisitation of one's own parenting role and possibly supporting the achievement of a psychosocial sense of integrity. In an interview study, grandsons shared the ways that their grandfathers helped them make meaning of fatherhood. In these conversations, themes included consciousness of the family's lineage, a sense of who they are and what they do as fathers, ideas about multigenerational family bonds, and intergenerational and intragenerational improvement (Bates & Goodsell, 2013). In all of these ways, grandparents transmit their generative concern.

In an analysis of the sources of vitality in later life, Erikson, Erikson, and Kivnick (1986) found that relationships with grandchildren played the following critical role:

> The major involvement that uniformly makes life worth living is the thought of and participation in their relationships with children and grandchildren. Their pride in their own achievement in having brought up their young, through thick and thin, and their satisfaction in the way these young have developed gives them, for the most part, deep gratification. With the arrival of grandchildren, they may identify themselves as ancestors, graduated to venerability. Listen to their voices as they trace their own ancestry and that of their children's traits: "She has her mother's fire, that first girl of ours. She has more energy and more projects than anyone. Come to think of it, my mother had that fire, too. And my wife's two grandmothers." "My son is a perfectionist, like me." "The kids are innately smart, like their father." (p. 326)

Grandchildren also stimulate older adults' thoughts about time, the changing of cultural norms across generations, and the patterning of history. In relating to their grandchildren as they grow up, grandparents discover elements of the culture that remain stable. Some familiar stories and songs retain their appeal

HUMAN DEVELOPMENT AND DIVERSITY

Intergenerational Relationships in Various Ethnic Groups

Grandparents play a variety of roles in U.S. families from remote and minimally involved to actively engaged. A cross-cultural perspective highlights the qualitatively different ways that grandparents are viewed in ethnic groups that emerge from a more collectivist orientation, and the central role that grandparents play in the socialization process and family support systems. Although the majority of U.S. families do not have three generations living together in one household, the presence of grandparents living with their grandchildren is more than twice as likely in African American, Asian American, and Hispanic American families than in European American families. This may, in part, be a result of the financial pressures on ethnic families, but it is also a result of a more collectivist outlook in which family and kinship relationships are central to the value system and priorities of many ethnic groups.

In an interview study of African Americans, Latin Americans, Filipino Americans, and Cambodian Americans, older adults (ages 50 and up) described the importance of mutual assistance and its critical role in fostering a sense of continuity across the generations. This can be especially important for immigrant families. Older adults provide care, guidance, and instrumental assistance for families, especially when there are young children in the home and the parents have to work (Becker et al., 2003). Immigrant families from collectivist cultures express a strong sense of family obligation, which has an intergenerational pull. Children and adolescents strive to respect and please their adult family members, and aging adults offer instrumental support, guidance, and affection to their children and grandchildren (Merz, Ozeke-Kocabaas, Oort, & Schuengel, 2009).

In many ethnic groups, the grandparent generation is highly revered. In others, the intimacy of the family's daily concerns extends to grandparents, aunts and uncles, and other kin (Burnett, 1999; Lockery, 1991). The following brief descriptions suggest the outlook of four U.S. ethnic groups on intergenerational relations. Each has a slightly different flavor.

African Americans value strong kinship bonds and a supportive extended family system. Caregiving responsibilities are shared among kin and non-kin as needed. Grandparents tend to support working parents by providing care to young children and are cared for in return. Their active role in the family often contributes a strong moral and religious strength and provides emotional support to the parent generation that reduces stress in the household (Pellebon, 2012).

Chinese Americans place a strong value on bringing honor to the family. Filial piety is one of the highest values, evidenced in a great sense of obligation, respect, and responsibility for parents. Contemporary Chinese American adolescents place a great deal of importance on treating their elders with respect, and spend more time assisting and being with their parents and grandparents than their Anglo age-mates (Wong, 2012).

Japanese American families value and promote a high degree of interdependence. The Japanese children feel a strong motivation to seek their parents' approval for their own self-esteem, and Japanese parents' sense of well-being depends heavily on their children's achievements. The intergenerational transmission of this mutual interdependence results in a deep sense of obligation for the care of aging parents. Retired parents may live with their adult child who takes on the leadership role for the family (Sakamoto, Kim, & Takei, 2012).

Puerto Rican and many other Latino cultures embrace the value of familialism, a sense of closeness and interdependence among members of the nuclear and extended family, which includes a deep respect for elders. Family members serve many functions, including socialization, protection, companionship, social and business contacts, and economic support. Puerto Rican families create a formal intergenerational link through the role of the *compadrazgo*, or godparent, who has

Chinese American families continue to feel closeness across generations. These family members obviously have a strong sense of affection for one another as they enjoy a relaxing day in the park.

HUMAN DEVELOPMENT AND DIVERSITY (continued)

a responsibility for the child's well-being through life (Negroni, 2012).

Critical Thinking Questions

1. If you have a living grandparent, describe your relationship. Summarize the impact that your grandparents had on your development at different stages. How has your ethnic or religious group shaped the way you view your aging family members and the quality of your relationship with them?
2. Summarize the idea of different styles of grandparenting. How do you think your grandparents conceptualize their role? Talk to them about the kind of grandparent they are and how they would like to be. How does their sense of themselves compare with how you think of them in their grandparent role? What are the implications of the similarities and differences in these conceptualizations?
3. For each American ethnic group discussed above, consider some likely tensions between the grandparent and the grandchild generation. Speculate about problems that might arise if the adult children and the grandchildren identify with American individualistic values and grandparents identify with more collectivist values.
4. Imagine yourself as a grandparent. Based on the information presented in the chapter, what kind of grandparent would you like to be? Why? How do you think having a grandchild would influence your psychosocial development?

from generation to generation. Certain toys, games, and preoccupations of children of the current generation are remembered by grandparents from their own childhood. Grandparents may become aware of changes in the culture that are reflected in new childrearing practices; new equipment, toys, games, and forms of entertainment; and new expectations for children's behavior at each life stage.

For example, when grandmothers were interviewed about their experiences of breastfeeding, it became clear that though many women wanted to be helpful to their adult daughters, they came from a generation where breastfeeding was not typically practiced. Some women had very negative memories of how their own mothers and grandmothers viewed breastfeeding as vulgar, unsanitary, or lower class. Others recalled resisting the negative pressure and going ahead with breastfeeding. These personal experiences were very salient as they tried to support and encourage their own daughters in an era when breastfeeding was much more highly valued (Grassley & Eschiti, 2011).

By maintaining communication with their grandchildren, older adults keep abreast of the continuities and changes in their culture that are reflected in the experiences of childhood. Through their grandchildren, adults avoid a sense of alienation from the contemporary world. The more involved grandparents are in the daily care and routines of their grandchildren, the more central they become to a child's sense of security and well-being. This kind of importance is a benefit not only to the child, but also to the older adult's assessment of personal worth. Over time, the grandparent–grandchild relationship has the potential for becoming increasingly meaningful as grandchildren mature into adulthood. This relationship, typically sustained through mutual personal choice, combines love, respect, mutual support, and a unique form of shared as well as diverging history (Crosnoe & Elder, 2002a; Kemp, 2005).

Some adults interpret the role of grandparent as an opportunity to pass on to their grandchildren the wisdom and cultural heritage of their ancestry. Through interactions with their grandchildren, grandparents can transmit cultural values, providing insights that they hope will guide and protect future generations and preserve something of the cultural heritage that they treasure from their own past (Quéniart & Charpentier, 2013; Thompson, Cameron, & Fuller-Thompson, 2013). In the process of fulfilling this role, older adults communicate the meaning of their life experiences to their grandchildren. Grandparents select many avenues to educate their grandchildren, influencing their thoughts and fantasies. Storytelling, special trips, long walks, attending religious services, and working on special projects are all activities that allow grandparents moments of intimacy with their grandchildren. Educating one's grandchildren involves a deep sense of investment in experiences and ideals that one believes to be central to a fruitful life.

In a variety of ways, the transition into grandparenthood can serve as an opportunity for personal growth. Through interactions with grandchildren, older adults have the opportunity to reflect upon and understand their place in the chain of generations, to gain new insights into their own character, and to expand their capacity for love and affection.

> The transition to grandparenthood enabled me to come to terms with my parenting and maybe to give myself another chance to give, influence and be an important figure in my grandchildren's lives. (first time grandmother) (Taubman Ben-Ari, 2012)

Grandparent Caregivers. Roughly 10 percent of U.S. children under the age of 18 live in households with at least one grandparent present. In comparison to other ethnic groups, African American and Asian American children are more likely than Anglo or Latino children to be living in households with one or both grandparents. For about one third of these children, their parents are the primary householders and one or more grandparents live

Jakob invited his grandmother to come to school with him. First she read a story to the class; then Jakob read one. Reading aloud is one of the things they have enjoyed doing together ever since Jakob was small.

at home with them (Ellis & Simmons, 2014). These grandparents are likely benefiting from some type of support or care from their adult children. They may also provide direct and indirect support for their grandchildren, including being home when the children return from school, taking care of the children when they are ill and the parents have to work, and taking over household tasks so that parents and children can have time together.

In the other two thirds of this group, the grandparents are the householders, suggesting that many grandparents are using their resources to help support their adult children and grandchildren. About 1.5 million children live with their grandparents with no parents in the household. These children are more likely to be living in poverty, without health insurance, and receiving some type of public assistance than are children who live in their grandparents' household with their own parents present (Ellis & Simmons, 2014). Among grandparents who have custody of their grandchildren, an estimated 40 percent cared for their grandchildren for 5 years or more (Abel, 2010). This is a long-term commitment when the adult children are unable to parent.

Many grandparents play an important role in supporting the development of their grandchildren during times of family stress (Goodman, 2003; Mills, Gomez-Smith, & DeLeon, 2005; Villar, Celdrán, & Triadó, 2012). In contemporary American society, grandparents are a potential resource that can becalled into active duty when certain difficulties arise for parents. In cases of parental divorce, grandparents often assume a central role in the lives of young children. Some custodial mothers move back home with their parents. Grandparents often assume more child care responsibilities during this time.

Grandparents also play a key role when their young, unmarried daughters become pregnant. The pattern of unmarried teen mothers living with parents is especially common in African American families (Minkler & Fuller-Thomson, 2005). Among young adult African American parents, the grandmother is most often viewed as the person to count on for child care assistance, advice, and emotional support (Hunter, 1997). These grandmothers may be young themselves, just entering middle adulthood, when they assume the grandparent role. The presence of grandmothers appears to affect the family atmosphere as well as the childrearing environment. Having a grandmother in the home allows the mother to be more flexible in managing daily demands, thereby reducing much of the stress that characterizes single-parent families.

Maternal employment is another condition in which grandparents are likely to give direct support. Increasingly, parents of young children call on grandparents to provide all or part of daily child care (Brandon, 2000; Goodfellow & Laverty, 2003). These grandparents are intimately involved in the lives of their grandchildren, directing significant energy, talent, and time to this role. For more information on resources for grandparents who are raising their grandchildren, visit the government website USA.gov, and search for the topic "grandparents raising their grandchildren." Resources differ by state.

Grandparents who take on primary responsibility for their grandchildren face challenges as well as experiencing satisfactions in this off-time role. Grandparents who are raising their grandchildren are likely to have fewer financial resources than other families. Many grandparents are working as well as caring for their children. They may have to support their grandchildren with little access to social and financial services that would be available to other low-income families or foster families because they do not have legal guardianship of their grandchildren.

Michael Newman/PhotoEdit

Increasingly, more grandparents fall into the involved category, taking on parenting responsibilities for their grandchildren on a daily basis.

Depending on their age and their own health, grandparent caregivers may feel they have less energy and that they are less effective when it comes to discipline strategies. In some instances, they face conflicts and ambiguities in the relationship with their adult children that create a negative interpersonal environment (Barnett, Mills-Koonce, Gustafsson, & Cox, 2012). Caregiver stress is associated with poverty, absence of social services or financial support for child care, loss of freedom, and lack of involvement with friends and interests outside their family circle. When the grandchildren have been exposed to chaotic or neglectful parenting, they may have physical and mental health problems that place additional strain on grandparent caregivers (Dunifon, 2013; Longoria, 2010).

In contrast to these stressors, grandparent caregivers may perceive that they are expressing their generative motives in caring for their grandchildren. They are in a unique position to form a close emotional bond with their grandchildren, helping their grandchildren to cope during periods of family disruption and preserving kinship and community ties (Bullock, 2005; Dolbin-MacNab & Keiley, 2006; Landry-Meyer, Gerard, & Guzell, 2005; Minkler & Fuller-Thomson, 2005).

Bill and Sharon Hicks were interviewed about raising their granddaughter, Brittany:

> "It has not been easy. Sometimes we feel a little bitter because our anticipated freedom has been taken away." But when asked if he and his wife would open their home to Brittany again, he answered: "Positively, yes! Brittany has been a shining light in our lives. She has forced us to stay young at heart. And that's not such a bad thing to happen." (Abel, 2010)

Loss of Grandparent–Grandchild Contact.

In contrast to the picture of an increasing role for grandparents in caring for their grandchildren, a growing number of grandparents are losing contact with their grandchildren as a result of parental divorce, conflict between the parents, death of an adult child, or adoption of a grandchild after remarriage. Disruption in the grandparent–grandchild relationship is especially likely when the grandparent's adult child is not named as the custodial parent after a divorce. In the 1980s, most states created statutes allowing grandparents to file for a legal right to enforced visitation with their grandchildren, even over parental objections. The laws differ from state to state, establishing different conditions under which grandparents may be granted visitation. In 1998, a law was passed to ensure that grandparents who have visitation rights in one state may visit their grandchildren in any state. However, in some states, earlier visitation laws have been overturned, finding that they interfere with parental rights regarding the rearing of their children. States vary in the possibility for legal recourse if grandparents are denied visitation with their grandchildren.

> In states that do allow grandparents to petition for visitation, the standard for determining whether or not visitation is awarded varies. Some states ask grandparents to prove that it is in the "best interest of the child" to have a relationship with them. Other states require grandparents to prove it will "harm" the child if they do not have a relationship. Proving harm is much harder than proving that it is in the best interest of the child to see grandparents. Unfortunately, there are also states that don't allow grandparents to petition the court for visitation with grandchildren under any circumstances. While some grandparents do obtain court-ordered visitation arrangements with their grandchildren, most do not. (Goyer 2009)

For more information about grandparent visitation rights, visit the website of the Foundation for Grandparenting (www.grandparenting.org/) or AARP (aarp.org) on grandparents' visitation rights.

Widowhood

Among those ages 65 to 74, 6.8 percent of men and 20 percent of women describe their marital status as widowed; by the ages 75 to 84 these rates increase to 15.6 percent for men and 43 percent for women (U.S. Census Bureau, 2015f, Table A1). For many adults, the psychosocial consequences of **widowhood** include intense emotional grief, loss of social and emotional support, and loss of material and instrumental support. Emotions of depression, anger, shock, and overall grief as well as yearning for the deceased partner are observed 6 and 18 months after the loss (Carr, House, Wortman, Neese, & Kessler, 2001). The nature and intensity of emotional reactions to this loss will vary depending on how much the partners relied on one another for instrumental and emotional support, and on the quality of their marital relationship prior to the death of one partner. Most older widowers remarry, whereas the majority of widows remain unmarried and live alone.

Widows.

Widows must learn to function socially and in their own households without the presence of a marriage partner. Adaptation to this role requires resilience, creative problem solving, and a strong belief in one's personal worth. A woman who is widowed at age 60 can expect more than 20 years of life in which to create a new, single head-of-household lifestyle.

In addition to bereavement, a number of stressors challenge the coping resources of widows. Studies of economic changes among widows show that many experience increased expenses just prior to widowhood, as well as decreases in their financial resources for years following widowhood (Fan & Zick, 2006; Gillen & Kim, 2009). Women who have never participated in the labor market during their married years may have no marketable skills and feel insecure about entering the labor force. They may be uninformed or uneasy about using social service agencies to meet their needs. For most women, the loss of their husband is most keenly felt as a loss of emotional support, as expressed in the following quote. "He is most apt to be mentioned as the person the widow most enjoyed being with, who made her feel important and secure" (Lopata, 1978, p. 221). The transition to widowhood may be especially difficult for those who have been caring for an ill partner, hoping for recovery yet observing constant decline (Bass & Bowman, 1990).

Despite the pain and grief that accompany widowhood, most women cope with it successfully. In a study of women ages 60 through 98 who had recently become widows, there was a high degree of self-sufficiency (O'Bryant & Morgan, 1990). The majority said they performed a variety of daily tasks, including transportation, housekeeping, shopping, preparing meals, personal care and hygiene, financial and other decisions, and providing financial support, without help from others. More than 30 percent said they managed their own home repairs, yard work, and legal questions without help. From this study, a picture emerges of older, widowed women functioning at a high level of independence and autonomy yet benefiting from assistance from others, especially their children, in specific domains, depending on where help is needed.

Research from other national samples in the United States, Australia, and Hong Kong confirm this picture. Resilience, which may be expressed in a variety of ways, including recovery of positive mood, engaging in new activities, or experiencing new levels of efficacy, are commonly observed in the months and years following widowhood. Women report that widowhood is a very difficult negative life event, but that after a period of bereavement they find themselves making a shift to a new, positive phase of adult life in which they both receive and provide social support to others (Cheng & Chan, 2006; Dolbin-MacNab & Keiley, 2006; Dutton Zisook, 2005; Feldman, Byles, & Beaumont, 2000; Ha, Carr, Utz, & Nesse, 2006).

Masterfile

Two long-time friends provide social support for each other. After they became widows, they moved into an apartment together to help manage costs. They're reviewing a box of bills and receipts as they get ready to do their income taxes. This also helps them reminisce about what they did during the past year.

Widows are likely to find support from their siblings, children, and friends. Over time, a widow's siblings, especially her sisters, may become a key source of emotional support and direct, instrumental assistance with home repairs and shopping. In an exploratory analysis of the responses of widows in a support-group discussion, comments about the positive and negative contributions of their social support network were analyzed (Morgan, 1989). The widows described their nonfamily, reciprocal friendship relationships as somewhat more positive than their family relationships. In many cases, widows found that as a result of their own sense of family obligation, they were drawn into negative events occurring in their families, especially divorce, illness, and the death of other family members. These negative events added to their distress and prevented them from receiving the support they felt they needed at the time of their own loss.

The analysis also concluded that the most positive form of immediate support from family, especially children, was a willingness to accept the widow's feelings of grief and to talk openly about their father. Social support from friends included a similar willingness to allow the widow to take her time in finding a new identity. These women did not want to be forced to mourn too quickly or be told how strong they were and how well they were handling their grief: "The fact that you're using the strength that you have, just to cope, and to stay alive (another voice: "to survive") is a big job and they don't recognize that, you know it makes you angry" (Morgan, 1989, p. 105). The widows wanted to have their anger, grief, and the disruption in their lives acknowledged and accepted by their friends. Then they felt they could begin to come to terms with their loss and build a new life.

Widowers. Widowers suffer greater increases in depression following the loss of their spouses than do widows (Lee, DeMaris, Bavin, & Sullivan, 2001; Umberson, Wortman, & Kessler, 1992). Perhaps because men in traditional heterosexual marriages rely heavily on their wives for the instrumental support of managing daily household tasks and the emotional and social support of companionship and social activity, their lives are more intensely disrupted when their wives die. However, many men are resilient, especially if the death of their partner occurs at an older age. Despite an initial painful period of grief and loss, these men are able to bring a sense of optimism and a positive outlook to their lives. They may cope by reorganizing their lives, by changing their environment, or by finding a new partner (Bennett & Soulsby, 2012).

In a 2-year follow-up study of dating and remarriage after the death of their spouses, 61 percent of men and 19 percent of women had remarried or were in a new romantic relationship by 25 months. For men, a higher monthly income and level of education were the best predictors of being remarried. For both men and women, involvement in a new relationship was positively associated with psychological well-being and interpreted as a positive coping strategy (Schneider, Sledge, Shuchter, & Zisook, 1996).

Widowhood is associated with increased death rates among surviving spouses. In a longitudinal study of married couples in the United States, the death of one spouse from any of a variety of causes, such as cancers, infections, and cardiovascular diseases, was associated with an increased risk of death for the surviving spouse (Elwert & Christakis, 2008). The process of bereavement seems to accelerate the course of preexisting diseases and leads to increased rates of suicides, accidents, and alcohol-related deaths. To some degree, the relationship of widowhood to mortality is tied to the well-known health effects of marriage. Depending upon the way that spouses support each other's health, the loss of a spouse may result in less effective adherence to medical care, less adequate diet, and less social interaction and social stimulation, all of which support physical and mental health in later life (Elwert & Christakis, 2006). In a meta-analysis of 15 studies, the relationship of widowhood to risk of mortality was found to be especially significant in the first 6 months following bereavement, and the risk was greater for men than for women (Moon, Kondo, Glymour, & Subramanian, 2011). Most adults cope successfully with widowhood, either by forming a new intimate relationship or establishing a new, independent lifestyle; however, others find it difficult to recover from the impact of their loss. The **Applying Theory and Research to Life** box on Patterns of Adaptation During Widowhood illustrates the variety of patterns of adaptation to widowhood.

Leisure Activities

As the role responsibilities of parenthood and employment decrease, older adults have more time and resources to devote to leisure activities. Involvement in leisure activities is associated with higher levels of well-being and lower stress.

Different types of leisure activities are available that meet a variety of psychosocial needs. Table 13.2 shows the percentage of older adults, ages 55 to 64, 65 to 74, and 75 and older, who participated in five types of leisure activities at least once in the prior year: exercise programs, playing sports, charity work, going to the movies, and gardening (U.S. Census Bureau, 2012b, Table 1202). Gardening tops the list in each of these age groups, with relatively little difference between those 55 to 64 and those 65 to 74.

A range of needs may be met through leisure pursuits, including companionship and social integration, experiencing something new and unusual, opportunities to enhance one's

APPLYING THEORY AND RESEARCH TO LIFE

Patterns of Adaptation During Widowhood

In a prospective, longitudinal study of widowhood, researchers surveyed married couples where the husband was 65 years old or older. Following the death of one partner, the surviving spouse was surveyed again at 6 and 18 months (Bonanno, Wortman, & Nesse, 2004). Five patterns of adjustment following the death of a spouse were described:

1. Common grief
2. Chronic grief
3. Chronic depression
4. Depression followed by improvement
5. Resilience

The most common patterns, for 56 percent of the sample, were common grief and resilience. These two groups had no signs of depression before the loss. The common grief group had evidence of depression at 6 months but returned to pre-loss levels at 18 months. The resilient group had low levels of depression even at 6 months following loss. Although these groups experienced fond memories and moments of yearning for their partners, they did not experience long-term grief at 18 months. A second, unexpected pattern, characteristic of about 10 percent of the sample, was a group that showed a change for the better following widowhood. The participants in this group had high levels of depression before the loss and lower levels at 6 and 18 months following the loss. Participants in this group were in unhappy marriages, and many of them had been caring for chronically ill partners. They reported being more confident and having found a new sense of personal strength in coping with the events of widowhood.

Two other groups were described as chronically grieving and chronically depressed. The chronically grieving group was not depressed before the death of their spouse but continued to show high levels of depression at 6 and 18 months following the death. These widows and widowers were often coping with the sudden loss of a healthy spouse and had trouble finding meaning in the death of their partners. The chronically depressed were already depressed prior to the death of their spouse. The death added a new stressor that increased their levels of depression at 6 and 18 months after the loss.

Subsequent studies of the transition from caregiver to widow support the idea that the conditions that surround the caregiving role and the quality of the marital bond, as well as the physical and mental health of the surviving spouse, will influence the coping process (Pruchno, Cartwright, & Wilson-Genderson, 2009). The majority of adults are able to cope effectively with the loss of a spouse. However, an understanding of the context of the loss and the emotional well-being of the surviving spouse before the loss are important factors that influence the bereavement process. Those striving to support widows and widowers need to be mindful of these differences in order to offer appropriate interventions.

Critical Thinking Questions

1. Summarize the contexts of widowhood that might determine how a person adjusts to loss.
2. Imagine that a person has spent several years caring for a dying spouse. Describe the aspects of role loss that might result upon the death of the spouse.
3. Consider the case of couples who have been happily married for 40 years or more. List the challenges of widowhood when one spouse dies. Identify the resources that might be useful to support adjustment under these conditions.
4. Explain how widowhood might influence the resolution of the psychosocial crisis of integrity versus despair for the surviving spouse, either positively or negatively.

Table 13.2 Participation in Various Leisure Activities by Age, 2008

	ACTIVITY* (% PARTICIPATION)				
Age Program	**Exercise**	**Play Sports**	**Charity Work**	**Go to Movies**	**Gardening**
55 to 64	52	17	33	46	52
65 to 74	48	13	30	32	55
75 and older	30	6	23	19	41

*Respondent has participated in the activity at least once in the last 12 months.

competence and mastery, finding solitude and relaxation, opportunities for creativity and self-expression, opportunities for intellectual stimulation, and opportunities for community service.

Gardening. There is growing awareness of the health and therapeutic value of gardening. Gardening provides regular physical activity, including stretching, coordination, and weight resistance. Depending on the size and demands of the garden, gardening can help an older adult meet the recommendations for half an hour of physical activity each day. Gardening requires planning, research, and problem solving. Preparing a garden, evaluating plants and their care, and monitoring their health and growth are natural forms of cognitive stimulation that can be enhanced with classes, books and magazines, and online resources.

Gardening is a stress-reducing activity, especially when approached in an appropriate pace and with tools that are well adapted to one's physical capacities. The sensory components of the garden, including smells, colors, and textures, can have a soothing, reassuring impact. Gardening can be an expression of generative motives, providing a lasting contribution to the community through the planting of public gardens or the enhancement of public spaces. Gardens are increasingly incorporated into senior centers and nursing homes to encourage cognitive, sensory, and motor activity and to provide a positive opportunity for exercising mastery. Master Gardener programs are sponsored by many universities where adult volunteers learn about up-to-date research-based information on horticulture to share with home gardeners and implement in the beautification of their communities (Morgan, 2005).

Volunteerism. In the United States, among those 65 and older, about 25 percent volunteer, giving a median of 90 hours annually of unpaid time (U.S. Bureau of Labor Statistics, 2013d). Especially in the year or two following retirement, individuals who are not already involved in volunteer service are especially open to considering it (Caro & Bass, 1997). **Volunteerism** provides a meaningful structure to daily life, especially when other significant work and family roles are becoming less demanding. Volunteering is associated with increases in life satisfaction and improved perceptions of physical health (Van Willigen, 2000). The opportunities to assume new responsibilities and learn new skills are two of the rewards of volunteering in later adulthood. At the same time, certain types of volunteer work have been shown to have a positive impact on cognitive complexity and memory functions.

Johns Hopkins University researchers compared the health of volunteer tutors in Baltimore's public schools with that of nonvolunteers, ages 59 to 86 (Fried et al., 2004). The following benefits were observed:

- Sixty-three percent of volunteers had increased their activity level, compared with 43 percent of nonvolunteers.
- Volunteers boosted their weekly calorie burn by 25 percent.
- Volunteers reduced TV-watching time 4 percent whereas nonvolunteers increased theirs by 18 percent.
- Their networks of friends expanded, whereas nonvolunteers' social circles shrank.
- Volunteers perceived that they were making a difference: The students they tutored became better readers, and had fewer behavior problems at school.

Expanded research built upon this study through collaboration with Experience Corps Project, a high-intensity volunteer program. Older adults were trained as volunteers to tutor elementary school children. The program combined goals to support health among older adults and reading competence among children. Studies of the health impact of this program on older adults across 17 national sites found evidence of significant health benefits and reduced symptoms of depression among volunteers as well as some evidence of increased neural activation in the prefrontal cortex and associated improvement in executive function (Carlson et al., 2009; Hong & Morrow- Howell, 2010; Park & Bischof, 2013).

Exercise. Physical exercise is becoming a focus of leisure activity for increasing numbers of older adults because the benefits are linked to better health and cognitive functioning, positive self-esteem, and a new zest for life. Almost 50 percent of adults ages 65 to 74 reported being involved in physical exercise during the prior 12 months. In a time use study reported by the Bureau of Labor Statistics (2016d), adults ages 65 to 74 reported engaging in sports, exercise, and related physical activities about 19 minutes a day during the week and 15 minutes on the weekends.

Research supports a clear relationship between physical activity—especially a regular pattern of aerobic exercise—and reduced atrophy of brain cells as well as better brain functioning and related cognitive abilities. "Physical activity takes advantage of the brain's capacity for plasticity," improving brain health (Erickson, Gildengers, & Butters, 2013). Improvements in cognitive function are associated with improved executive control processes mood and well-being (Kramer & Willis, 2002).

In the past, professionals were reluctant to encourage vigorous activity for older adults. They believed that a person who was unaccustomed to active physical exercise might be harmed by it. However, research on exercise in adulthood suggests that adults profit from a program of exercise, and that through systematic exercise, some of the negative consequences of a sedentary lifestyle can be reversed (Riebe, Burbank, & Garber, 2002).

Physical exercise is a component of optimal aging. Regular participation in moderate activity, such as walking, biking, or gardening, for 30 minutes a day may provide protection from certain chronic diseases and ease the discomfort of arthritis (DiPietro, 2001). Exercise is associated with increased muscle tone, strength, and endurance, which build confidence about one's body movement, coordination, and stamina. Exercise also increases perceptions of self-control and self-efficacy in meeting one's own needs. As a result, people who exercise tend to have a generally more positive self-evaluation and higher levels of self-confidence than their inactive peers (Clark, Long, & Schiffman, 1999; Fontane, 1996). Many community organizations and agencies are exploring group fitness programs to engage older adults in regular exercise. Group programs have the benefit of providing valued social interaction as well as a regular schedule of meetings and a clear routine of aerobic, strengthening, balance, and flexibility exercises. Research on participant perspectives in one such program highlights the value of the social nature of these classes as well as the practical benefits for improving participants' ability to manage daily activities at home (Kohn, Belza, Petrescu-Prahova, & Miyawaki, 2016).

Redirection of energy to new roles in later adulthood requires a degree of flexibility and resilience that often goes unnoticed in observations of older adults. Try to imagine what life might be like for you 30 or 40 years from now. We are impressed by how readily most older adults adapt to new roles, especially those of retiree and widow, for which there is little early preparation or social reward.

FURTHER REFLECTION: *Describe some of the challenges of redirecting energy to new roles in later adulthood. What might prevent a person from giving up earlier identities or engaging in new activities?*

Speculate about the relationship between life satisfaction and redirecting energy to new roles. If you are satisfied with your life, why would you want to redirect energy to new roles? If you experience significant role loss, will it undermine life satisfaction?

Think about the nature of leisure activities. What are you doing now that you expect to continue into later adulthood? What activities might you "pick up" or engage in when you reach later adulthood that create new cognitive demands and thereby support well-being?

Developing a Point of View About Death

OBJECTIVE 4 Summarize the development of a point of view about death.

During later adulthood, it is inevitable that serious, possibly frightening, preoccupations about death fill the individual's thoughts. In middle adulthood, most people experience the death of their parents. During later adulthood, one's peers, including siblings and spouses, may die. These deaths typically evoke grief and mourning as well as the cognitive strain of trying to accept or understand them. At the same time, these deaths stimulate a more immediate recognition of one's own mortality. Although death can occur at any stage of life, in this section we focus on the psychosocial work that is likely in later adulthood as one confronts the possibility of one's own death. In chapter 15, we review the research on death, dying, and bereavement within the broader biological, psychological, and cultural perspectives, considering the experiences not only of the dying person but also of those left to mourn.

Changing Perspectives About Death

The development of a perspective on death is a continuous process that begins in childhood and is not fully resolved until later adulthood. The earliest concern with death, which occurs during toddlerhood, reflects an inability to conceive of an irreversible state of lifelessness. Toddlers are likely to think that a person may be dead at one moment and "undeaded" the next. By middle school age, children have a more realistic concept of death, but they are unlikely to relate that concept to themselves or to others close to them (Kastenbaum, 2000). A conceptualization of death becomes increasingly accurate from early through later adolescence (Noppe & Noppe, 1997). In the process of forming a personal identity, young people ask new questions about mortality, the meaning of life, and the possibility of life after death.

During middle adulthood, people recognize that they have already lived more than half of their lives. Death becomes increasingly concrete as parents and older relatives die. At the same time, middle adults have a larger impact on their families and communities. Increased feelings of effectiveness and vitality lessen the threat of death. The degree to which individuals gain satisfaction from their own contributions to future generations influences the extent of their anxiety about death during this stage. The achievement of a sense of generativity usually allows adults to accept that their impact will continue to be felt even after death.

In the 1960s, Elisabeth Kübler-Ross engaged in groundbreaking work to understand the thoughts, feelings, and needs of patients who were dying. Through her interviews with more than 400 patients, she clarified a process of coping with one's death. She identified five stages that are likely to occur between the awareness of a terminal illness and ultimate acceptance of one's death: denial, anger and resentment, bargaining for a reprieve, depression and mourning one's death, and acceptance or a willingness to face the reality of one's death. She also discovered how eager most people were to have someone who would listen to their thoughts and how grateful they were to interact with someone about their death rather than have it treated as a taboo or unmentionable topic (Kübler-Ross, 1969/1997 reprint edition, 1981/1997 reprint edition).

Subsequent research suggests that there is no single, typical path in the dying process. Some people alternate between accepting and denying their death. They understand their situation, yet fall into periods of disbelief. Some people are able to bring what they view as an acceptable close to their life, saying good-bye to family and friends, and finding comfort in the support of others.

Others die while still in a state of fear or denial (Kastenbaum, 1985, 2012). Kübler-Ross's stages are neither a universal nor fixed sequence, but they provide a useful model for considering the dynamic ego processes that are engaged as one faces death. The capacity to confront the reality of death can be a profound occasion for new insight.

Ideally, during later adulthood, ego concerns about death decrease. Individuals come to accept their own lives as they have lived them and begin to see death as a natural part of the life span. Death no longer poses a threat to personal value, the potential for accomplishment, or the desire to influence the lives of others. As a result of having accepted one's life, one can accept its end without discouragement. As the case of Morrie Schwartz suggests, coming to terms with death does not imply a desire for, but an acceptance of the fact of death. Along with this acceptance may come a greater appreciation for life itself. It takes great courage to face the fact of one's own death and, at the same time, to live out the days of one's life with optimism and enthusiasm (Kübler-Ross, 1969, 1972).

— CASE STUDY Morrie Schwartz Reflects on His Views About Death —

Mitch Albom, in his 40s, rediscovered his former college professor Morrie Schwartz, who was dying from amyotrophic lateral sclerosis (ALS), a progressive neurological disease that attacks body muscles and leaves one increasingly paralyzed. Mitch and Morrie met every Tuesday for the last 4 months of Morrie's life.

"Everyone knows they're going to die," he said again, "but nobody believes it. If we did, we would do things differently."

"So we kid ourselves about death," I said.

"Yes. But there's a better approach. To know you're going to die, and to be *prepared* for it at any time. That's better. That way you can actually be *more* involved in your life while you're living."

"How can you ever be prepared to die?"

"Do what the Buddhists do. Every day, have a little bird on your shoulder that asks, 'Is today the day? Am I ready? Am I doing all I need to do? Am I being the person I want to be?'" He turned his head to his shoulder as if the bird were there now.

"Is today the day I die?" he said. . . .

"The truth is, Mitch," he said, "once you learn how to die, you learn how to live." I nodded.

"I'm going to say it again," he said. "Once you learn how to die, you learn how to live." He smiled, and I realized what he was doing. He was making sure I absorbed this point, without embarrassing me by asking. It was part of what made him a good teacher.

"Did you think much about death before you got sick?" I asked.

"No." Morrie smiled. "I was like everyone else. I once told a friend of mine, in a moment of exuberance, 'I'm gonna be the healthiest old man you ever met!'"

"How old were you?"

"In my sixties."

"So you were optimistic."

"Why not? Like I said, no one really believes they're going to die."

"But everyone knows someone who has died," I said. "Why is it so hard to think about dying?"

"Because," Morrie continued, "most of us all walk around as if we're sleepwalking. We really don't experience the world fully, because we're half-asleep, doing things we automatically think we have to do." . . .

"Mitch. Can I tell you something?"

"Of course," I said.

"You might not like it."

"Why not?"

"Well, the truth is, if you really listen to that bird on your shoulder, *if you accept that you can die at any time*—then you might not be as ambitious as you are." I forced a small grin. "The things you spend so much time on—all the work you do—might not seem as important. You might have to make room for some more spiritual things."

"Spiritual things?"

"You hate that word, don't you? 'Spiritual.' You think it's touchy-feely stuff."

"Well," I said.

He tried to wink, a bad try, and I broke down and laughed. "Mitch," he said, laughing along, "even I don't know what 'spiritual development' really means. But I do know we're deficient in some way. We are too involved in materialistic things, and they don't satisfy us. The loving relationships we have, the universe around us, we take these things for granted."

He nodded toward the window with the sunshine streaming in. "You see that? You can go out there, outside, anytime. You can run up and down the block and go crazy. I can't do that. I can't go out. I can't run. I can't be out there without fear of getting sick. But you know what? I *appreciate* that window more than you do."

Case Analysis Using What You Know

1. Summarize the point of view about life and death that Morrie is developing.
2. Analyze what this conversation suggests about Morrie's psychosocial development, including how issues of intimacy, generativity, and integrity are reflected in this dialogue.
3. Hypothesize how the conditions of Morrie's illness might influence his outlook on death.
4. Describe the issues you would want to discuss if you had a mentor like Morrie who was willing to help you learn about living and dying.

The formulation of a **point of view about death** requires the capacity to absorb the loss of one's close relatives and friends and to accept one's own death. The former task may be even more difficult than the latter, in that the death of peers begins to destroy one's social group. Losing one's friends and relatives means losing daily companionship, a shared world of memories and plans and a source of support for values and social norms. The circumstances surrounding the deaths of others may also be very frightening. Older adults observe their peers suffering through long illnesses, dying abruptly in the midst of a thriving and vigorous life, or dying in absurd, meaningless accidents. After each death, the surviving adults must ask themselves about the value of these lives and subsequently about the value of their own life.

Death Anxiety

Fear of personal death, or **death anxiety**, is natural and normal. Death may be feared for a variety of reasons, some of which relate to the actual process of dying and others to the consequences of it. Concerns about dying include fears of being alone, being in pain, having others see one suffering, or losing control of one's mind and body. Concerns about the consequences of dying include fears of the unknown, loss of identity ("People will forget about me"), the grief that others will feel, the decomposition of the body, and punishment or pain in the hereafter (Tomer & Eliason, 2000).

Several researchers have considered the sources of personal anxiety about death and the changes in preoccupation with death at various ages. Although older adults seem to think about death more frequently than do young adults, they do not appear to feel more threatened by it. In comparison to middle-aged adults, older adults experience lower death anxiety (Sinoff, Iosipovici, Almog, & Barnett-Greens, 2008). Among the elderly, it appears that those who have higher levels of self-worth and sense of mastery also have lower levels of death anxiety (Ron, 2010). In comparison to those in early or middle adulthood, those in later adulthood know more people who have died and are more likely to have visited a cemetery or attended a funeral. Those in later adulthood are more likely to have made some specific arrangements related to their death, including purchasing cemetery space, writing a will, or making plans for their funeral. Their concrete experiences with the events of death, coupled with their own sense of mastery in preparing for their death, may allow them to cope more effectively with their fears (Cicirelli, 2001).

What factors help older people cope with fears about death? Psychosocial theory predicts that through acts of generativity, people experience satisfaction in guiding and nurturing future generations. Achieving a positive resolution to the psychosocial crisis of generativity versus stagnation should help reduce death anxiety. One study designed to test this hypothesis found that the relationship of generativity to the fear of death was mediated by ego integrity, the positive pole of the crisis of later adulthood. Among those who were described as generative, the older adults who had high levels of ego integrity had the least fear of death, supporting the theoretical notion of a progressive integration of ego strengths from one stage of life to the next (Bringle, 2007).

In addition to the achievement of a generative orientation, people who describe themselves as religious may be less troubled by the fear of death. Most religions offer a point of view about death, as well as death-related rituals and practices that help structure this great unknown. Those who have a strong social support system, and those who have a strong sense of self-worth are less likely to be preoccupied with the fear of death (Tomer & Eliason, 2000). Frey (2003) extended this perspective by focusing on the relationship of self-beliefs to death anxiety. Older adults who have a positive sense of spiritual self-efficacy, perceived ability to generate spiritually based faith and inner strength, have less fear of the unknown following death and less fear of the pain and suffering associated with dying.

Charles Mistral/Alamy Stock Photo

The ritual of a graveside service helps mourners separate from their loved one before the burial. Many elements of a traditional funeral are depicted here: the flowers, the tombstone, and the mourners gathered and supporting each other in a tree-lined cemetery.

FURTHER REFLECTION: *Developing a point of view about death may be one of the most universal tasks across cultures. What are the societal resources that help people address their mortality? What are the most helpful ideas you have encountered in your life so far that will aid you in dealing with the challenges of this task?*

The Psychosocial Crisis: Integrity Versus Despair

OBJECTIVE 5 Define and explain the psychosocial crisis of integrity versus despair, the central process of introspection, the prime adaptive ego quality of wisdom, and the core pathology of disdain.

On entering later adulthood, adults draw on the competence and creativity attained during middle adulthood to invent solutions to their changing conditions. You may appreciate the common theme of a search for meaning, especially a desire to understand one's purpose in life, between the psychosocial crisis of later adolescence and the psychosocial crisis of later adulthood. In later adolescence, young people strive to create a coherent vision of the self in society that will guide future choices. In later adulthood, adults strive to reconcile and accept the events of their life. At this stage, adults apply the wealth of their life experiences, their perspective on time, and their adaptation to life crises to construct personally satisfying answers to the questions of life's meaning.

The conflict of integrity versus despair is resolved through a dynamic process of life review, introspection, and self-evaluation. Contemporary factors, such as health, family relationships, and role loss or role transitions, are integrated with an assessment of one's past aspirations and accomplishments. Thoughts of the past may be fleeting or a constant obsession. Memories may be altered to fit contemporary events, or contemporary events may be reinterpreted to fit memories. The achievement of integrity is the culmination of a life of psychosocial growth. It is the peak of the pyramid in that it addresses the ultimate question, "How do I find meaning in life given the ultimate reality of death?"

Integrity

The term **integrity**, as it is used in psychosocial theory, refers to the ability to accept the facts of one's life and face death without great fear. As people get older, they need to find a way to integrate or reconcile the events of their life with the hopes and dreams they may have had in their early or middle adulthood. This process of meaning making involves an assessment of one's life and the extent to which worthwhile goals were sought and achieved. In a search for life's meaning, a person looks for a way to assemble a coherent story of order, purpose, and value out of the complex puzzle pieces of a life (Krause, 2004; Reker, 1997). The sense of meaning in life provides a higher order belief that can unify many disparate experiences, give direction to life decisions, and contribute to an overall feeling of well-being. People differ in what they find meaningful and where they realize the greatest personal inspiration including such dimensions as achievement, relationships, religion, self-transcendence, self-acceptance, intimacy, and fair treatment. These sources of meaning can motivate action, increase commitment and persistence, and add a sense of enjoyment to life (Macdonald, Wong, & Gingras, 2011).

The attainment of integrity is ultimately a result of the balance of all the psychosocial crises that have come earlier, accompanied by all the ego strengths and core pathologies that have accumulated along the way. Integrity comes only after some considerable thought about the meaning of one's life. Older adults who have achieved a sense of integrity view their past in an existential light. They appreciate that their lives and individuality are due to an accumulation of personal satisfactions and crises. Integrity is not so much a quality of honesty and trustworthiness—as the term is used in daily speech—as it is an ability to integrate one's past history with one's present circumstances and to feel content with the outcome.

Most people have some regrets. One may look back and wish that one had taken advantage of certain opportunities, been smarter about saving or investing money, or spent more time with one's children while they were young. The challenge in achieving integrity is to face the decisions and experiences of the past with acceptance. In this process, a person seeks to find an integrative thread that makes sense of the life one has led without belaboring past mistakes. The concept of **sense of coherence** has been linked to integrity and well-being in later life (Antonovsky, 1987; Wiesmann & Hannich, 2011). People who view their lives as understandable, manageable, and meaningful are thought to benefit from this sense of coherence. It is a construct that combines a cognitive ability to make sense of life experiences, an emotional optimism that things will, by and large, work out favorably, and a behavioral component that involves taking steps to achieve desired goals (Eriksson & Lindstrom, 2005).

Given the abstract and subjective construct of integrity, how can it be measured? A variety of approaches have been developed (Hearn, Saulnier, Strayer, Glenham, Koopman, & Marica, 2011). One approach, devised by Neil Krause (2007), provides a four-dimensional measure of meaning in life. These dimensions include (1) having a system of values, (2) having a sense of purpose, (3) having goals to strive for, and (4) reflecting on the past to reconcile one's accomplishments with one's goals. Taken together, these four dimensions comprise a meaning in life scale. In a longitudinal study of older adults, Krause examined how various forms of social support as well as anticipated social support related to meaning in life over a 4-year period. Those older adults who received high levels of emotional support had higher meaning in life, but those who received tangible support had lower meaning in life. Anticipated support, that is, believing that you could call upon close family and friends for help if it were needed, was the strongest predictor of meaning in life. Over time, anticipated support was also a significant predictor of changes in a person's sense of meaning.

When older adults are confident that they will be able to count on others for help in the future, their sense of meaning in life is bolstered. This finding speaks to the role of the radius of significant relationships in predicting and sustaining a sense of integrity in later adulthood. It also suggests a continuing role for trust and hope, the very earliest psychosocial concepts of infancy, in fostering integrity in late life.

In addition, research suggests a link between generativity and integrity. Older adults who have made meaningful contributions to the quality of life for future generations can draw on these experiences to find meaning in their own lives. As suggested by the data on volunteerism, for many adults generative action continues into later adulthood and extends beyond care for one's immediate family to concern about the larger community (Ehlman & Ligon, 2012; Schoklitsch & Baumann, 2012).

Despair

The opposite pole of integrity is **despair**, a feeling of regret about one's past and a continuous, haunting desire to be able to do things differently, or of bitterness over how one's life has turned out. People who resolve the crisis of later adulthood in the direction of despair cannot resist speculating about how things might have been or what actions might have been taken if conditions had only been different. They are preoccupied with the *if-onlys* of their past, without any hope of altering or repairing these regrets in the future. Despairing individuals either seek death as a way of ending a miserable existence or desperately fear death because it makes impossible any hope of compensating for past failures.

In response to the interview question, "Overall, how do you feel your life has gone so far?" a despairing woman gave the following answer:

> Well, (sighs), it could have been worse. I'm satisfied.
> I've had a lot of problems, and ah, yes, there are regrets.
> That's life. I don't think you're supposed to be happy
> on earth. If you're happy you're lucky. Or if you get
> everything you want you're lucky. I haven't had a happy

> marriage and I always felt that I could have, you know that there must be. . .my husband is not a man that I can lean on, and in my younger days I wanted somebody to lean on because I lost my father and there was no father figure in my life. (Hearn et al., 2011, p. 5)

Most older adults do not resolve the psychosocial crisis of later adulthood in the direction of despair. Over a long life, most people have opportunities to review and redefine earlier life challenges in a way that makes them seem acceptable. Recall the U-shaped curve of life satisfaction. At older ages, people generally experience less anger and sadness, and a more positive sense of well-being. At the same time, there are experiences and societal contexts that may contribute to periodic feelings of disappointment and regret.

Older adults may face some degree of **ageism**—devaluation and even hostility from the social community. The negative attitudes expressed by family members, colleagues, and younger people toward the perceived lack of competence, dependence, slowness, or old-fashioned ways of older people may lead some later adults to feel discouraged about their self-worth. The gradual deterioration or loss of certain physical capacities—particularly hearing, vision, and motor agility—may add to an older person's frustration and discouragement. Older adults recognize that they cannot perform certain tasks as well as they did in the past or that their domains of independent functioning and mastery have diminished.

Furthermore, there is a general cultural sentiment that the death of an older person—in contrast, for example, with the death of a child or youth—though sad, is not a great loss to society, because that person had already contributed to society and lived a full life. Thus, older adults may perceive that society is already letting go of them, even before they are ready to let go of life (Jecker & Schneiderman, 1994).

Depression

People who are in a state of despair are also more likely to experience **depression** as well as problems with perceived ill health (Hearn et al., 2011). However, depression is not a normal aspect of aging. Nearly 8 percent of all people in the United States aged 12 and older (6 percent of males and 10 percent of females) reported moderate or severe depressive symptoms in the past 2 weeks. Females had higher rates of depression than males in every age group. Middle adulthood appears to be the peak for the incidence of depression. Males aged 40 to 59 had higher rates of depression (7 percent) than males aged 60 years and older (3.4 percent). Females aged 40 to 59 had higher rates of depression (12 percent) than females aged 60 years and older (7 percent) (Pratt & Brody, 2014).

Many of the same factors that are associated with depression in younger age groups are associated with depression in older age groups: poverty, poor physical health, lack of social involvement, and being single, divorced, or widowed. The risk of depression in later life cannot be attributed to the aging process itself. The physiological changes associated with aging—such as high blood pressure, reduced breathing capacity, reduced muscle strength, slower reaction time, memory loss, and loss of visual or auditory acuity—are not associated with depression in and of themselves (Hinrichsen & Clougherty, 2006). However, some of these conditions or the medications that are given to address these problems may trigger feelings of depression. The symptoms of depression may look somewhat different among older adults; less evidence of sadness or feelings of worthlessness, and more complaints of being tired, having trouble sleeping, being irritable, or having trouble concentrating (National Institute of Health, 2016; Mayo Clinic, 2016).

Older adults who have a clear sense of coherence about life, those who view their situation as comprehensible, manageable, and meaningful, are more likely to be resilient in the face of chronic physical illness than those who view their lives as chaotic and out of their control. Depression as a complex affective and cognitive syndrome does not automatically come with the territory of aging. However, it is especially likely among those who have experienced decreased activity level associated with pain or illness; death of a loved one and associated loss of significant, close, confiding relationships; and accumulated physical health problems that limit their independence and dampen their sense of enthusiasm for pleasant activities (Wiesmann & Hannich, 2013).

The Central Process: Introspection

In order to achieve a sense of integrity, a person must engage in **introspection**, a deliberate process of private, personal reflection and self-evaluation. The achievement of a sense of integrity requires the ability to introspect about the gradual evolution of life events and to appreciate their significance in the formation of adult personality. This state can be reached only through individual effort. It may require temporary isolation, shutting out the influences of potentially competitive or resentful associates, or deliberately stepping away from daily tasks in order to have time to relax and think. A national survey of time use finds that the time spent relaxing and thinking increases with age, from just under 7 minutes a day for those in their early 20s to 22 minutes a day in the period of later adulthood (Bureau of Labor Statistics, 2016d).

One mode for engaging in self-evaluation is **reminiscence**, the recollection of past experiences and the recalling or retelling of memories from long ago. This process of nostalgic remembering allows adults to recapture some of the memorable events in their life histories. Reminiscence may be a playful recalling of a life adventure or a painful review of some personal or family crisis. The process of reminiscence is comprised of four elements: the *selection* of an event or story to retell or review; *immersion* in the details of the story, including the strong emotions linked to the event; *withdrawal* from the past by distancing oneself from the event or comparing past and present; and bringing *closure* to the memory by summing up, finding some lesson, or making a general observation. Through this process, a person builds a mental and emotional bridge between the past and the present (Meacham, 1995).

Michael Newman/PhotoEdit

The process of nostalgic remembering allows adults to recapture some of the memorable people and events in their life histories.

Reminiscence is linked to positive adjustment in later life, especially better health, a more positive outlook, and a better ability to cope with the challenges of daily life (Kunz & Soltys, 2007). However, not all forms of reminiscence are of equal benefit. In particular, reminiscences of the integrative or instrumental type tend to be associated with high levels of well-being, whereas obsessive reminiscences are not. Integrative reminiscence involves reviewing one's past in order to find meaning or to reconcile one's current and prior feelings about certain life events. Instrumental reminiscence focuses on the past, on accomplishments, efforts to overcome difficulties, and experiences to help cope with current difficulties. *Obsessive reminiscence* suggests an inability to resolve or accept certain past events and a persistent guilt or despair about them (Korte, Cappeliez, Bohlmeijer, & Westerhof, 2012; Wong & Watt, 1991). Contrast the following two narratives:

> When I was a teenager, my parents broke up and both remarried. I was very resentful because they did not seem to care about my feelings or needs. But as I grow older and look back, I understand that they were really not compatible with each other. They had suffered for many years before their divorce. [Integrative reminiscence]

> My husband died when I was away for two days visiting my friends in the West. He fell in the bathtub and eventually died because there was no one there to help him. It has been years now, but I still cannot forgive myself for leaving him home alone for two days. [Obsessive reminiscence] (Wong & Watt, 1991, p. 276)

Reminiscence lends continuity to older adults' self-concepts. They can trace the path of their own development through time and identify moments that were of central importance in the crystallization of their personal philosophies. Through reminiscence, older adults can revise the meaning of past events by using current wisdom to understand or accept what took place in the past. For example, reminiscence was encouraged in a group of veterans who had been involved in the Normandy invasion at the end of World War II. The veterans retold their experiences of loss, grief, and shock and how those experiences influenced their lives over the subsequent 50-year period. Formulating their experiences in a story-like format and retelling their stories to others provided a means of coping with the stressors of this past experience (Harvey, Stein, & Scott, 1995).

Reminiscence serves as an integrating process that has positive value in an eventual attainment of integrity. In a review of 20 studies with older adults who suffered from depression, guided reminiscence was found to be as effective as drug treatment or psychotherapy for alleviating depressive symptoms (Bohlmeijer, Smit, & Cuijpers, 2003). In excess, however, reminiscence can dominate reality, taking over the time and energy that might be directed toward more appropriate active social involvement. Some adults dwell on sad events and allow earlier disappointments to preoccupy their current thoughts. Their past lives take precedence over their current circumstances. No new events can compete successfully with past memories for their attention.

The benefit of introspection for well-being and the sense of integrity depends on the person's ability to cope with the material that was called up from the past. Two effective coping strategies that have been linked to mental health in older adults are assimilative and accommodative coping. In assimilative coping, the person recognizes the significance of past events and their links to important life goals. This provides a positive sense of continuity, affirming the focus and meaning of life events, even if the past events were troubling. In accommodative coping, the person recognizes the need to revise his or her appraisal of the situation. The person realizes how the difficult events of the past led to the modification of goals which, in turn, created a new and valued sense of meaning (Cappeliez & O'Rourke, 2002; Cappeliez & Robitaille, 2010).

The Prime Adaptive Ego Quality and the Core Pathology

Wisdom

Erikson identified wisdom as the prime adaptive ego quality of later adulthood. It reflects a concern for life and a desire to learn and communicate essential lessons from experience in the face of impending death (Erikson et al., 1986).

Wisdom has been characterized by six features (Ardelt, 2004; Baltes, Smith, & Staudinger, 1992, p. 272; Bangen, Meeks, & Jeste, 2013; Kramer, 2003; Staudinger, Dorner, & Mickler, 2005):

1. *Factual knowledge* about fundamental life matters, such as general knowledge about the human condition and specific knowledge about life events, their age-related occurrence, and their expected and unexpected course.
2. *Procedural knowledge*, composed of strategies for approaching the management and interpretation of life matters, including linking past, present, and future.
3. *Life-span contextualism*, approaching problems with the realization that events are embedded in a multidimensional context—including age-related, culturally defined, role-related, and sociohistorical frameworks—and that events take their meaning from certain distinct domains, especially family, work, and leisure.
4. *Relativism of values and life goals*, allowing the person to appreciate differences among individuals and societies with respect to the priorities they place on certain values, as well as the ability to preserve a certain core of universal values.
5. *Recognition and management of uncertainty*, incorporating the realization that the future cannot be totally predicted and that many aspects of the past and present are not fully known, plus an ability to manage and cope with this uncertainty.
6. *Self-insight*, including self-understanding, a sense of humor, and emotional balance (e.g. self-control and emotional regulation).

One concept that helps link the idea of intelligence in later adulthood with the ego strength of wisdom is **expertise**. With age, individuals who focus their intelligence in intensive study, training, and repeated opportunities for problem solving within a domain become *experts*. A variety of intellectual processes support expertise, including deductive reasoning, a rich and complex working memory, and the ability to organize large amounts of information for storage and subsequent recall. We rely on experts to help inform important and difficult decisions. We see experts as having wisdom in their particular specialization. Although we may be inclined to look to experts in one field to help us solve a wide range of problems, the assumption behind expertise is that it is discipline specific. In that sense, expertise and wisdom are not identical (Horn & Masunaga, 2000; Masunaga & Horn, 2001).

Not all people who live to old age function at a high level of wisdom. However, studies that compare younger and older adults find that there are contexts in which older adults demonstrate a greater degree of insight and problem-solving skill. When asked to analyze situations involving intergroup and interpersonal conflicts, older adults made greater use of advanced reasoning, multiple perspectives, and the need for compromise than younger adults. They also more readily acknowledged the limits of their knowledge and the need to take the specific context into account when predicting the outcome of the situation (Grossmann et al., 2010). There is a path toward increasing wisdom among certain individuals who are especially able to find insights about life from their daily experiences (Ardelt, 2010; Choi & Landeros, 2011).

Jose Galvez/PhotoEdit

Joseph looks forward to these quiet talks with his father. He knows he will always come away with new insight about planning, managing, or understanding the challenges he is facing in his own life.

Three dimensions that have been hypothesized to promote wisdom are (1) opportunities to experience a wide variety of life situations and circumstances; (2) encouragement by a mentor or guide to expand one's capacity for thinking about problems from a multidimensional, psychohistorical perspective; and (3) a strong generative orientation or desire to continue to gain insight into how people meet the challenges of life (Baltes & Smith, 1990).

Disdain

Wisdom reflects flexibility of thought, openness to new interpretations, and a willingness to accept the complexity of life. In contrast, **disdain** refers to feelings of contempt for ideas or people who are viewed as inferior or unworthy. Disdain conveys rejection and scorn for ideas and persons and an arrogance that implies one's own opinions and views are superior. It can be understood as a defensive response to the repulsion for one's physical self and failed past. Disdain for others may be a mechanism to enhance one's own status and prestige. Rather than becoming more patient, more compassionate, more forgiving, and less critical in their later life, older adults who develop disdain are more likely to disparage others and detach from the world around them (Erikson et al., 1986).

FURTHER REFLECTION: *Explain how reminiscence and introspection contribute to the resolution of the psychosocial crisis of integrity versus despair. What experiences from earlier stages might contribute to a person's ability to reflect upon and evaluate the meaning of her or his life?*

What is your own definition of wisdom? Where do you seek wisdom? What wisdoms would you want to pass along to others that might help them cope with life's uncertainties and achieve a sense of well-being?

The psychosocial perspective assumes that new growth takes place at every stage of life. Summarize the new directions for growth in later adulthood.

Applied Topic: Retirement

OBJECTIVE 6 Apply theory and research to understanding the process of adjustment to retirement.

Retirement is a societal and psychological construct that has a variety of definitions. One definition is that the person works less than full-time year round and receives income from a retirement pension earned during earlier periods of employment. Some people define retirement as the time at which people begin to receive Social Security or other pension benefits, regardless of their employment status. However, retirement also refers to a psychosocial transition involving role loss and role gain—a time for redirecting energy to new roles, new opportunities to promote intellectual vigor, and new sources of life satisfaction. As one withdraws from the formal structure of work and alters one's occupational identity, the transition brings increased time for reflection about the meaning and purpose of one's life. To the extent that work has provided a basic structure for one's lifestyle, withdrawal from the structure and significance of paid employment can be replaced by other activities, new relationships, and a new sense of purpose.

Of course, some people never retire, some die before they reach retirement age, and others continue to work on a part-time schedule. Some people of retirement age leave their primary job and take another full-time or part-time job in a related field or in a totally different one. Many adults who are self-employed or whose work involves creative skills, such as acting, music, painting, or writing, continue to work into their late adulthood. Projections from the U.S. Bureau of Labor Statistics indicate that in the coming years there will be an increasing involvement of older adults in the labor force. Table 13.3 shows the percentage of men and women at two ages, 65 to 74 and 75 and older, who were in the labor force in 1994, 2004, and 2014, as well as projections for 2024. Over the 20 years from 1994 to 2014, the rate of labor force participation increased for both men and women at both ages and is projected to continue to rise in the coming 10 years. By 2024, about one third of men and one fourth of women in later adulthood will be working, and a substantial subset of elders (10 percent of those 75 and older) will continue their labor force participation. Thus, although retirement will still be normative in later life, a growing segment of the older population will be working (U.S. Bureau of Labor Statistics, 2015).

Income Loss

Much of the information about retirement planning and the decision to retire focuses on financial considerations (USA.gov, 2016). Based on data regarding life expectancy, for those who reach the age of 65, there may be another 20 to 25 years of life ahead. Think about what is required to support 25 years of retirement during 40 years of paid employment. Most financial planners suggest that there is about a 25 percent to 30 percent reduction in income after retirement, which is somewhat greater for those who retire before age 65. Although work-related expenses, taxes, and child care expenses may decrease, health and recreational expenses may increase. In addition to reduced income, not all the sources of income are adjusted to keep pace with inflation. Thus, the value of retirees' fixed income declines over time (USA.gov, 2016).

Older householders' annual income is derived from five primary sources: Social Security, property and other assets, pensions, earnings, and supplemental security income (Social Security Administration, 2016) (see FIGURE 13.4 ▶). Access to these various resources varies by race and ethnicity, with older Whites having greater access to personal assets and pensions, and Asian Americans and Hispanics drawing more on supplemental security income due to their poverty status. In 2014–2015, the median income for households headed by someone 66 years old and older was $38,515. This can be compared to a median household income of $73,857 for a household headed by someone ages 45 to 54. About 9 percent of individuals 66 years and older had incomes below the poverty level. Poverty is greater for older minorities and older adults who live alone (Proctor, Semega, & Kollar, 2016).

Economic factors account, in part, for why people are staying in the labor market for a longer time. The age at which one can receive full Social Security benefits has increased to an older age for more recent cohorts, and there is no penalty for continuing to work after the normal retirement age. Many employer-provided retirement benefits have shifted from guaranteed pension plans to defined contribution plans, so that workers can continue to contribute to their retirement fund for every year they work. Employer-sponsored health care benefits after retirement have decreased, so there is an incentive to continue working until one reaches the age at which Medicare benefits are available (Mermin, Johnson, & Murphy, 2007). Factors including grandparents who are the primary caregivers for their grandchildren, unemployment or underemployment of children in middle adulthood, and the poor quality of benefits associated with many jobs contribute to financial decisions to continue in the labor market in later adulthood.

Adjustment to Retirement

Adjustment during the retirement transition is an individual process. Although we think of retirement as an event, it is really a long period during which people have to clarify their sense of

Table 13.3 Civilian Labor Force Participation Rates by Age and Sex for 1994, 2004, 2014, and Projections for 2024

	1994		2004		2014		2024	
	Men	Women	Men	Women	Men	Women	Men	Women
65–74	21.7%	13.6%	26.7%	18.0%	30.6%	22.4%	34%	26.2%
75+	8.6%	3.5%	9.0%	4.3%	11%	5.9%	13.5%	8.4%

purpose and meaning, and redefine the nature of their daily activities. Adjustment to retirement is expected to change with time. Atchley (1999) proposed phases of anticipation, transition, and eventual adaptation to retirement. Four markers in this process include (1) a *honeymoon* period, which is busy and positive; (2) a *disenchantment* or letdown phase, in which the meaning and structure of work are missed; (3) a *reorientation* phase, in which a more realistic lifestyle is created; and (4) a *stable* period, which may last 10 or 15 years until changes in health, financial resources, or one's social support system require a significant revision.

Most older adults cope effectively with the changes associated with retirement, viewing it as a desired transition (Atchley, 2003). In retrospect, however, they often realize that preparation for retirement should have included more emphasis on the psychosocial aspects of this change rather than focusing so exclusively on its financial impact. Nancy Schlossberg (2009) refers to this as assembling a "Psychological Portfolio" in which a person articulates and clarifies aspects of identity, relationships, and sense of purpose that will serve as resources during the post-retirement years. In her research, she characterized seven paths through retirement and beyond that capture differences in how people shape their future lives:

1. Continuers: They maintain their former identity, but in a modified way. They stay connected to their former work and work-related identities while expanding in new directions.
2. Adventurers: They pursue an unrealized dream or try something new.
3. Easy-gliders: They take each day as it comes; no agenda and no pressures.
4. Involved spectators: They are still psychologically involved in their former life but are no longer active in it.
5. Searchers: They are looking for their special niche, exploring, and then moving on.
6. Retreaters: They are stepping back, taking a break to decide what to do next.
7. Disengaged: They are depressed, uninvolved, and unable to find a path forward.

Benefits of Retirement

What do people look forward to in retirement? Weiss (1997) described a longitudinal study of men and women who were over age 63 and intended to retire in the coming year or had recently retired. Most anticipated that retirement would bring a reduction in stress, especially in coping with the challenges and crises of the workplace. Workplace conditions such as lack of challenge, reorganization, and downsizing (with its accompanying increased demands on the remaining employees) are stressors that workers are glad to leave behind when they retire (Henkens & Tazelaar, 1997). According to the American Time Use Survey, retirees have a newfound 7–8 hours of leisure time each day. They use this time in many ways including getting more sleep; watching more TV; doing household maintenance including lawn and garden care, cooking, and housework; working for pay; eating more slowly and lingering over meals with family and friends; shopping, including comparison shopping; volunteering and participating in spiritual, civic, or community activities; reading; using the Internet for entertainment, information, and contacting others; socializing with friends, family, and neighbors; relaxing and thinking; and exercising (Brandon, 2016).

People who come to retirement from a context of lifelong well-being are likely to adapt well to this transition. They have had experiences of goal attainment, management of their time, effective social support, and invigorating intellectual stimulation, which

Mark Bowden/Getty Images

Using his knowledge of camping and exploration of the out-of-doors, Grandpa Victor teaches his grandchildren how to build a fire from gathered twigs, bark, and small branches. Victor loves being with his grandchildren and now that he is retired, he spends as much time as possible with them.

provide continuing resources after retirement. We can imagine that they will fit into one of the positive pathways described above and find a satisfying direction (Halleröd, Örestig, & Stattin, 2013).

Difficulties with Retirement

In contrast to those who are adjusting easily, a subset of retirees report declines in life satisfaction, especially those who experience significant income loss, poor health, or death of a spouse, events that are age-related and may not be attributed specifically to retirement. Approximately one third of adults report significant difficulties during this process (Pinquart & Schindler, 2007).

Perceptions of retirement involve a person's enthusiasm, positive anticipation, or resentment about it. These perceptions are linked to the ways in which work structures one's lifestyle throughout early and middle adulthood. In addition to the obvious functions of paid employment—especially income and social status—a number of latent functions provide important psychological benefits (Jahoda, 1982; Lo & Brown, 1999). Work provides a structure for the use of time; a context for social contact; a content for self-identity; regular, predictable activities into which one can channel intellectual, physical, and emotional energy; and a sense of participation in a collective effort. If retirement is perceived as resulting in deprivation in these areas, it presents a threat to psychological well-being.

The concept of **retirement anxiety** refers to apprehensions that adults have as they anticipate retirement (Fletcher and Hansson, 1991; Osborne, 2012). Sharpley (1997) found that when retirees reflected on factors that caused them stress in everyday living, three areas emerged: missing work, problems with personal health, and relationship issues. Psychological aspects of retirement that can create anxiety include identity disruption, a loss of a sense of meaning or purpose, uncertainty about ways to continue to engage meaningfully in society, and the loss of meaningful social relationships. For those who suffer from retirement anxiety, two factors were especially troubling. First, people worried about the loss of structured social involvement and connection. This concern was linked to worry about losing friendships, being lonely, and having little in common with former coworkers after retirement. Second, people worried about having to be assertive or proactive in finding new relationships and activities that would meet their needs. This concern was linked to a general difficulty in handling life transitions, a high level of uncertainty about the future, and a general feeling of loss of identity. Although one might think that people who have high levels of retirement anxiety would use services that help people plan for retirement, this was not the case. They may try to deny this transition by avoiding planning and counseling sessions.

In addition to worries about being unable to meet social needs following retirement, some adults experience anxiety because they feel a lack of control. People have expectations about how long they plan to work and at what age they will retire. When people perceive that they are working or not working by their own choice and that they can determine how much work to do, they have higher levels of health and well-being. However, when they perceive that their level of involvement in work is being decided by someone else and have little say in it, they are likely to have more difficulty adjusting to retirement, more health problems, and a greater incidence of depression (Gall, Evans, & Howard, 1997; Schultz, Morton, & Weckerle, 1998). Especially for men who expect to work on into their late 60s and are forced into retirement, this lack of control over exiting from the workplace is predictive of lower well-being and reduced life satisfaction (Clarke, Marshall, & Weir, 2013).

— **CASE STUDY** Anna Quindlen Writes About Retiring as "Stepping Aside" for the Next Generation of Writers —

Anna Quindlen, who wrote "the last word" for Newsweek for 9 years, explains why it's time for her to move on.

The baby-boom generation has created an interesting conundrum for this country. Born between 1946 and 1964, boomers take up more room than any other generation in American History. They now account for about a quarter of the population. And so, inevitably, they have created a kind of bottleneck, in the work world, in politics, in power. The frustration this poses for the young and talented should be obvious. In my personal life it was reflected powerfully on the day when, talking of the unwillingness of my friends to retire, my eldest child noted, "You guys just won't go." . . .

Today we have an entire generation of Americans who seem dedicated to the proposition that they will fight aging to the death. Quite literally. And that means staying front and center professionally.

The unspoken synonym for "emeritus" is "old." And old is a word we don't even use anymore in polite conversation, a modern obscenity. . . .

I believe that many of our old ways of doing things are out of date, including some of our old ways of looking at, and reporting on, the world around us. Since the day he delivered his Inaugural Address, when I was 8 years old, people have been quoting the youthful John F. Kennedy saying that the torch had been passed to a new generation. But torches don't really get passed very much because people love to hold on to them. . . .

If I had any lingering doubts about giving it up after almost nine years, they were quelled by those binders on my desk, full of exemplary work by reporters young enough to be my children. Flipping through their pages, reading such essential and beautifully rendered accounts of life in America and around the world, I felt certain of the future of the news business in some form or another. But between the lines I read another message, delivered without rancor or contempt, the same one I once heard from my own son: It's our turn. Step aside. And now I will.

Case Analysis Using What You Know

1. Explain how the developmental tasks of later adulthood are reflected in this narrative.
2. Evaluate the accuracy of Ms. Quindlen's analysis about the reluctance of the baby boom generation to retire. Discuss the factors that might account for the baby boom cohort's approach to retirement.
3. Summarize the ways the psychosocial crises of generativity versus stagnation and integrity versus despair are related to Ms. Quindlen's decision to retire.

Retirement for Couples

From a systems perspective, it makes sense to think about adaptation to retirement in the context of the other life roles one is playing. One of the most relevant is the marital relationship. With the large number of dual earner couples, it is important to consider the impact of retirement for a couple as well as for the individual. Retirement transitions can involve one partner remaining in the labor market when the other retires, both partners retiring at about the same time, and one or both partners retiring from their primary work and becoming involved in secondary work after retirement. These configurations can have consequences for the couple's marital satisfaction because the change in work status affects their relationship.

The Cornell Retirement and Well-Being Study focused on workers and retirees ages 50 to 72. Participants were interviewed once in 1994–1995 and again in 1996–1997. Among the people in this sample, 25 percent were not yet retired and their spouses were also not yet retired. For another 36 percent, both the respondent and the respondent's spouse were retired. In the remainder, one spouse was working and the other spouse was retired. Several observations were made about marital quality during this transition. First, both men and women reported decreases in marital quality when they moved from work to retirement. The role transition from work to retirement appears to have a short-term negative impact on the marriage. Second, if one spouse remains in the labor market and the other retires, the retired partner reports more marital conflict. In this case, the stress of the role transition from work to retirement seems to be compounded by the lack of synchrony between the partners in the structure of their daily lives (Moen, Kim, & Hofmeister, 2001). The greatest satisfaction with retirement was reported by couples where both partners were retired, and the wives said that their husbands did not influence their decision to retire (Smith & Moen, 2004).

In an AARP national survey of individuals who were married (or living as married) and were retired or had a partner who was retired, couples where both spouses were retired were happier than couples where one partner was still in the labor force. Although the retirement decision is often treated as an individual one, in about one third of cases where one partner retired first, that person encouraged the other partner to retire. For some couples, dissatisfaction with retirement tended to spill into the marital relationship. Individuals who were dissatisfied with retirement also said their relationship with their partner was weaker. This lack of satisfaction could be a product of another underlying issue such lack of control or purpose. For most couples, retirement was positively associated with more travel, more exercise, volunteering, and involvement in hobbies (Kopper, 2008).

The Future of Retirement

A combination of demographic, economic, and organizational changes are contributing to more varied, flexible alternatives to full retirement (Lytle, Clancy, Foley, & Cotter, 2015). Certain social forces are influencing continuing involvement in the labor market after age 65. An increasing number of businesses are eliminating a mandatory retirement age. In 2000, the earnings limit for receiving full Social Security benefits after age 65 was lifted. Finally, the age for full eligibility for Social Security retirement benefits will rise to 67 for those born in 1960 or later. At the same time, movements toward reducing labor force participation for older workers include the development of early retirement plans, phased retirement, part-time work, and reduced or redefined job expectations. Innovation in retirement options seems to be taking two directions at the same time: how to retain older workers in meaningful work roles and how to permit more flexible earlier retirement programs (AARP, 2000).

Several long-range concerns suggest a need to reexamine the right to retirement concept. Prospects for a longer, healthier adulthood mean that a large proportion of the population will be out of the labor force for nearly one third of their adult lives if people continue to retire fully at age 65. Between 2010 and 2030 the large baby boom generation will reach retirement age, placing new demands on the Social Security system and new expectations for services to support quality of life. With a reduced fertility rate in Generation X, there may not be enough younger workers available to support this large nonworking population. If adults work to an older age, they will continue to contribute to the Social Security system, which will keep it financially sound for a longer time.

Among older adults who are well educated and have enjoyed working, many want to continue some of their positive experiences through constructive work. They do not want to retire, and with the lifting of the mandatory retirement age, they do not have to. It is not uncommon for men and women to take new jobs, perhaps with fewer or more flexible hours after they retire from their primary work. A great majority of these older workers remain in the labor market by choice. In a national survey of people ages 50 to 70 sponsored by AARP, nearly 70 percent thought that age 65 or older was an ideal age to retire, 37 percent said they would continue some type of paid work when they retired from their current job, and 6 percent said they thought they would never retire (Anderson, 2015). Reflecting on the next phase of their "post-retirement" career, the following features of an ideal job were mentioned: working part-time, working from home, opportunities for travel, helping others, and earning a good income from their work. Couples often want to coordinate their retirement. Since men typically marry younger women, they may continue working to an older age until their wives reach age 65.

People who reenter the labor force during midlife or make major career changes then want to persist in these new activities in order to fulfill achievement goals. Many women who delayed their entry into the labor market or achieved a professional degree after their spouse had completed his degree want to extend their work life into their late 60s and 70s (Austria, 2012).

The current cohort of workers who are now in their 50s and 60s have become used to a more fluctuating work history, moving from one company or employer to another. They are more accustomed to taking charge of their occupational career rather than relying on the built-in career ladder of a single occupation or employer. The idea of switching companies or occupations is a more familiar process for current workers, giving them confidence to retire from one position, withdraw from work for a while, and start over somewhere else. Technologies that allow people to work from home increase the chances that older workers, especially those who are well-educated, can continue to participate in the paid labor force. At the same time, fluctuating labor-market conditions create the risk that older workers who want to reenter the job market will not be able to find suitable employment (Rosegrant, 2013). Thus, just as the earlier generations grew accustomed to expecting to retire, new generations of older adults are finding ways to prolong their productive work lives, negotiating new and innovative ways of making transitions in and out of the paid labor force.

FURTHER REFLECTION: *Given the information and evidence you have read about later adulthood, what are your thoughts about retirement? Is age a relevant factor in deciding when to retire? If not, what other factors should a person consider?*

What is your own plan regarding retirement? Do you expect to retire? How does work fit into your sense of life satisfaction? How important is work to your personal identity? Describe an approach to retirement that inspires you.

CHAPTER SUMMARY

Variability in the patterns of adjustment during later adulthood results from the interaction among biological, psychological, and societal factors including personality characteristics, health, coping strategies, ego strengths, social support, and the range of life circumstances. Certain regularities can be anticipated in the termination of old roles and the establishment of new ones. The tasks of later adulthood—accepting one's life, promoting intellectual vigor, redirecting energy to new roles and activities, and developing a point of view about death—require a balance among investments in past, present, and future.

OBJECTIVE 1 Examine the construct of life satisfaction in later adulthood and analyze factors associated with subjective well-being.

There is an expectation that energy will be spent in the evaluative process of reviewing and accepting one's past achievements. However, this focus on the past must be complemented by the enactment of new roles, the resolution of new problems, and efforts to find new, engaging challenges in the present. People who are extroverted, optimistic, experiencing a sense of usefulness, and who feel they are in control of events in their life are also likely to experience high levels of satisfaction. Development in this period of life requires an ability to selectively direct resources to optimize functioning in the areas of life that are of primary value and satisfaction. Studies of life satisfaction and well-being find evidence of a U-shaped curve in which well-being reaches a low point in middle adulthood and rises in later adulthood and elderhood.

OBJECTIVE 2 Define intellectual vigor, and describe factors that promote it in later life. Evaluate evidence about the interaction of heredity and environment on intelligence in later life.

Genetic factors contribute to the stability of cognitive capacities over the life course, whereas the impact of the environment, including access to social support, engagement in challenging work and social relationships, health, and education all contribute to variability in cognitive functioning. Certain abilities, especially general knowledge and verbal abilities, remain relatively unchanged with age, whereas speed of processing and numeric abilities tend to decline. These patterns differ depending on overall intelligence of the person, the career focus, and expertise of the individual. Research in cognitive neuroscience provides evidence of both decline in brain functions with age, and continued plasticity, depending on health, and repeated engagement with demanding tasks.

OBJECTIVE 3 Explain the process of redirecting energy to new roles and activities, with special focus on role gain, such as grandparenthood; role loss, such as widowhood; and new opportunities for leisure.

The nature of the grandparent role differs across cultures, and within cultures across families. No single type of grandparent–adult child–grandchild relationship is normative in the United States, but most are characterized by feelings of affection and agreement about basic opinions and values. Adaptation to widowhood also varies across individuals and between men and women. Men are more likely to remarry, women to live alone after the death of their spouse. The pattern of adjustment depends heavily on the quality of the relationship before the partner died and the conditions surrounding the partner's death. Leisure time represents another domain in which there can be both role gain and role loss. Leisure activities can serve a wide range of physical, cognitive, and interpersonal goals. Volunteerism, through which later adults make substantial contributions to their communities, also has the potential for sustaining cognitive functioning and subjective well-being.

OBJECTIVE 4 Summarize the development of a point of view about death.

In later adulthood, people's thoughts about death tend to become more practical, focusing on the preparation of a will and planning for one's burial. However, anxiety about death seems to diminish with age. A strong sense of generativity and integrity contribute to the ability to face death with less fear while continuing to find joy in the satisfactions of daily life.

OBJECTIVE 5 Define and explain the psychosocial crisis of integrity versus despair, the central process of introspection, the prime adaptive ego quality of wisdom, and the core pathology of disdain.

The psychosocial crisis of integrity versus despair captures the courage and creative synthesis required in later adulthood. In the face of an increasingly evident mortality, experiences in physical changes, role loss, and the death of peers, most older adults are able to define and articulate the thread of meaning in their lives. They are able to look back with satisfaction at past achievements and with acceptance of past failures. The central process of introspection acknowledges the need for self-awareness as well as time for reflection in order to carry out the psychological work required to reach a sense of integrity. In this process, many older adults find a certain practical wisdom that is shared with others and becomes their legacy for the future.

OBJECTIVE 6 Apply theory and research to understanding the process of adjustment to retirement.

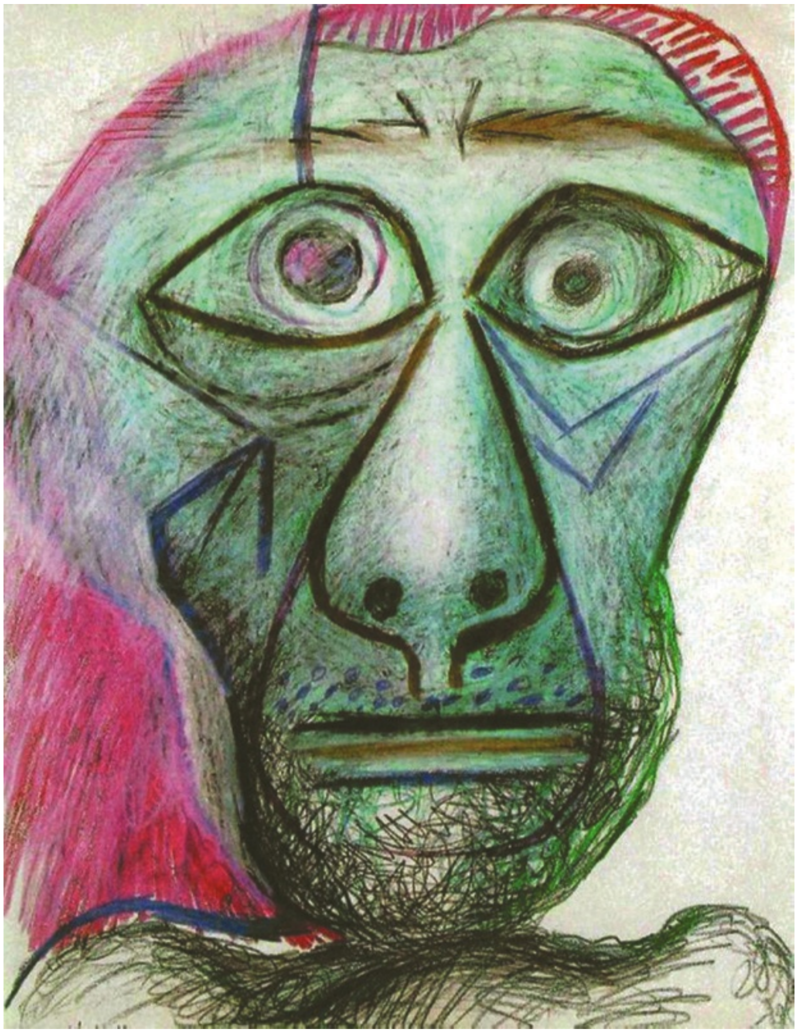
The role transitions that accompany retirement illustrate the challenge of later adulthood. Retirement usually results in leaving a major life structure—one that provided social status, focus, purpose, and economic resources. The potential loss of daily stimulation poses threats to both cognitive and social functioning. Because so much of one's social status is linked to occupational attainment, leaving a work role is almost like giving up a social identity. Older adults face numerous adjustments after retirement, including role loss. They must restructure their lives so that they continue to feel pride in past achievements without dwelling on the past, and so that they seek new and realistic opportunities for making use of their talents in the present. With the prospect of a long, healthy later adulthood, many in the current cohort of older adults expect to continue participation in the paid labor force even if they intend to change jobs or shift their occupational focus.

It is critical to be sensitive to the image that children, adolescents, young and middle-aged adults, and older adults themselves have of later adulthood. One should not underestimate the impact that one's perceptions of later life have on well-being and optimism at every earlier life stage. If the later years hold no promise, all earlier stages will be tainted with a sense of desperation. On the other hand, if the later years can be anticipated with optimism, people will be free at each earlier stage to experience life in a more confident, accepting manner.

CASEBOOK

For additional case material related to this chapter, see the case of "Lola," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 209–212.

This case focuses on the role of reminiscence in resolving the psychosocial crisis of integrity versus despair and the opportunity for earlier expertise to be used in redirecting energy to new roles.



2011 Estate of Pablo Picasso/Artists Rights Society (ARS), New York

At the age of 91, shortly before his death, Picasso painted this remarkable self-portrait. He faces his death with eyes wide open—no pretenses, some fear, some wonder.

LEARNING OBJECTIVES

1. Explain the rationale for identifying elderhood as a unique developmental stage for those of unusual longevity with its own developmental tasks and psychosocial crisis.
2. List the physical changes associated with aging, and evaluate the challenges that these changes pose for continued psychosocial well-being.
3. Describe the concept of a psychohistorical perspective, an altered perspective on time and history that emerges among the long-lived.
4. Summarize elements of the lifestyle structure in elderhood, especially living arrangements and gender roles, and analyze the impact of these life structures for continued well-being.
5. Define and explain the psychosocial crisis of immortality versus extinction, the central process of social support, the prime adaptive ego quality of confidence, and the core pathology of diffidence.
6. Apply research and theory to concerns about meeting the needs of the frail elderly.

Chapter Summary

— **CASE STUDY** Fred Hale, Supercentenarian —

Fred Hale was born December 1, 1890, in New Sharon, Maine. His biography and photo portrait are included in a book on "supercentenarians," people who have lived to be 110 or more.

Earth's Elders: The Wisdom of the World's Oldest People, by Jerry Friedman.

Perhaps the most amusing story from Fred came about when he was 107 and still living on his own. At that age, he was the world's oldest licensed driver.

There had been a heavy snowfall in Maine and Fred was up on his porch roof shoveling off the snow. When he finished, he hopped off into a snow bank and then went into his house to change his wet clothes. Suddenly he noticed there were flashing lights outside. When he opened the door, there were the firemen and police who'd come to his rescue. When he was told that a passerby had seen someone fall of the roof, Fred quipped, "I didn't fall, I jumped" and slammed the door.

Fred has been confined to a wheelchair and the assisted care facility after he tripped and broke his hip. That hasn't dulled his mind however. He still jokes and plays cards with his son of eighty. He read a little and loved to watch the Red Sox. Clearly, he was the oldest Red Sox fan in the world. When asked why he had lived so long he jibed, "Oh, I don't know, punishment I guess. I've enjoyed all my years, each one. I even like the recent one."

The last time we spoke I asked, "If there was one piece of wisdom you'd like to pass on to your grandchildren what would it be?"

"You have one life to live, live it well, and don't disgrace your family."

Source: Jerry Friedman, 2005, p. 80.

CASE ANALYSIS Using What You Know

1. Summarize your assumptions about the lifestyle and behaviors of elders. How does this case confirm or disconfirm those assumptions?
2. List five of Fred's personality characteristics. Explain how these qualities may contribute to longevity.
3. Analyze Fred's final wisdom. What are the implications of this advice for you and your family? For others in your generation?

Pablo Picasso, whose works illustrate this book, lived to be 91 years old. When he was 79, he married Jacqueline Roque with whom he enjoyed 12 years of married life. During the last 20 years of his life, he remained productive and energetic, persistently experimenting with new art forms and ideas.

Here are some other examples of people who achieved major accomplishments after the age of 80 (Wallechinsky & Wallace, 1993; Wallechinsky, Wallace, & Wallace, 1977):

At 100, Grandma Moses was still painting.
At 99, twin sisters Kin Narita and Gin Kanie recorded a hit CD single in Japan and starred in a television commercial.
At 94, George Burns, who won an Oscar at age 80 for his role in *The Sunshine Boys*, performed at Proctor's Theater in Schenectady, New York, 63 years after he had first played there.
At 93, George Bernard Shaw wrote the play *Farfetched Fables*.
At 91, Eamon de Valera served as president of Ireland.
At 91, Hulda Crooks climbed Mount Whitney, the highest mountain in the continental United States.
At 89, Arthur Rubenstein gave one of his greatest piano recitals in New York's Carnegie Hall.
At 88, Konrad Adenauer was chancellor of Germany.
At 87, Mary Baker Eddy founded the *Christian Science Monitor*.
At 81, Benjamin Franklin provided leadership for the political compromises that led to the adoption of the U.S. Constitution. ●

The Longevity Revolution

We have entered a period in which increasing numbers of people are living into old age. As the previous examples illustrate, it's not that we have no models of the long-lived in earlier periods of history, but that so many more adults are living into their 80s and 90s than ever before. In 2016, 6 percent of the U.S. population was 75 and older, and as the baby boomers (those born between 1946 and 1964) mature, this age group is expected to reach 11 percent of the population. In 1980, more than 2 million people were 85 and older; by 2015, this group had grown to 6.2 million (U.S. Census Bureau, 2016). At the 2010 census, 53,364 people were 100 years and older. The 85-and-older population is the fastest-growing age group in the United States (Werner, 2011).

The 20th century was unique in human history in the large percentage of people who lived well beyond their reproductive and childrearing years into later adulthood and elderhood. This new facet of life raises questions about the pattern of mortality after achieving reproductive success and about what, if any, limit there might be to the human life span. Current projections suggest that in the United States the average life expectancy at birth will be 80 by the year 2020 (U.S. Census Bureau, 2010e). Genetically based diseases that emerge only in the second half of life, such as breast and colon cancer or adult-onset diabetes, become more common as larger numbers of people reach advanced age. At the same time, the mapping of the human genome along with medical and technical innovations hold the promise of preventing some of the diseases now associated with later life. Life expectancy is most influenced by interventions that prevent infants and children from dying, ensuring that more people reach advanced ages of 70 or older. Interventions that influence the life expectancy at ages 70 and older increase overall life expectancy by only a few years. Nonetheless, significant discoveries that might prevent death from cancers or cardiovascular diseases could affect large populations and continue to extend human longevity.

The human species is a highly complex organism designed to survive over a relatively long period in order to find a mate, reproduce, and rear and nurture the young until they are old enough to reproduce. From an evolutionary perspective, the adaptive value of life after this sequence is not well understood. One hypothesis

Jeanne Calment, who died in 1997 at the age of 122, was the world's longest living person whose birth date could be verified. Mme. Calment liked chocolates, smoked cigarettes, and had a wonderful sense of humor. Here she displays her Guinness certificate acknowledging her record-winning longevity.

is that the extended family—composed of grandparents as well as parents—provides more resources for the support of the young and forms an added protective layer against crises that might leave the younger generation vulnerable (Baudisch & Vaupel, 2012).

It is clear that there is a genetic basis to longevity. Studies of centenarians (people 100 years old and over) find a relatively large number of genetic markers involving over 130 genes that predict extreme longevity. These markers become increasingly accurate in predicting which individuals will live to advanced ages of 100 and older. Studies of these centenarians find three different patterns of resilience that are associated with longevity. One group has many of the same diseases of aging before age 80 as those who are not so long lived, but they recover and continue on to advanced age. One group has delayed age-related illness after the age of 80. And one group had no age-related illnesses even at age 100. Genetic factors contribute to the compression of illness toward the very end of life and enhanced capacities for recovery (Andersen, S. L., 2012; Sebastiani et al., 2012).

The current cohort of elders (those 75 and older) includes the older group from the greatest generation (sometimes called the GI Joe generation) born between 1910 and 1925, and the younger group from the silent generation, born between 1925 and 1945. The greatest generation grew up during the Great Depression; many men served during World War II, and many women worked in factories in order to sustain war-related production. Over 400,000 U.S. deaths were attributed to war-related military actions, civilian deaths related to military actions, and disease associated with the war. The harsh and stressful conditions of the war are known to have shortened the life expectancy of those who served in battle. Following a period of economic and war-related hardships, the survivors, both veterans and civilians, went on to rebuild the country in a spirit of optimism and patriotism.

The silent generation, most of whom were too young to serve in World War II, experienced the war during their childhood. In the 1950s, during the McCarthy anti-communist era, the atmosphere was one of suspicion and suppression of criticism of government. This generation was socialized to accept society, to adopt a conservative outlook, and to work hard at a time of economic recovery. They entered the labor market in a time of economic growth, formed families at an early age, and adopted traditional gender roles (Howe, 2014; Robinson, 2016).

Each new cohort of the very old will benefit from the information and technologies that are being developed. The more knowledge is gained about the biological processes of aging and the genetic basis of diseases and health that emerge in later life, the more likely it is that human longevity can be extended. Those adults in the current baby boom generation (born between 1946 and 1964) are quite likely to be high school graduates, to have benefited from many of the health-related innovations of the late 20th and early 21st centuries, and to be even more vigorous than our current older population. The projections of increased numbers of people reaching advanced age are due to improvements in health care and fitness and to the size of the baby boom cohort.

Secrets to Longevity

The very long lived, like Jeanne Calment, inspire others to ask about the factors that contribute to a long life. Jim Heynen (1990) interviewed 100 people who were 100 years or older. He found wide variations in their lifestyles and philosophical perspectives. Some of the advice they offered on how to live a long life follows:

> "Mind your own business, have a good cigar, and take a shot of brandy." *Brother Adelard Beaudet, Harrisville, Rhode Island*
> "I've lived long because I was so mean." *Pearl Rombach, Melbourne, Florida*
> "I always walked several miles a day. I'd talk to the flowers." *Mary Frances Annand, Pasadena, California*
> "Don't smoke before noon. Don't drink or smoke after midnight. The body needs 12 hours of the day to clear itself." *Harry Wander, Boise, Idaho*
> "I've been a tofu eater all my life; a mild, gentle man, never a worrier." *Frank Morimitsu, Chicago, Illinois*
> "I picked my ancestors carefully." *Stella H. Harris, Manhattan, Kansas*
> "Regular hours, taking it easy, smiling, whistling at the women when they walk by." *John Hilton, Fort Lauderdale, Florida*

A team of nutritionists, psychologists, physicians, and gerontologists interviewed 12 Cuban men and women who were reported to be more than 100 years old about their daily diets and lifestyles. The one theme they all agreed upon was the importance of an optimistic outlook on life. The coordinator of the meeting, Dr. Eugenio Selman, said that the six basic elements to longevity are (1) motivation to live, (2) appropriate diet, (3) medical attention, (4) intense physical activity, (5) cultural activities, and (6) a healthy environment. In this analysis, one sees the interaction of the biological, psychological, and societal systems (CNN.com, 2005). Surprisingly absent from this list is the role of social integration and social support. A growing literature highlights the contribution of a sense of belonging to overall health and resilience in the face of crisis (Gow et al., 2007).

The Blue Zone

The Blue Zone refers to specific geographic areas of the world where people are known to live a long, healthy life. Early work by Poulain et al. (2004), identified an area of Sardinia in Italy where a large number of men were found to live to 100 years and more. Following this research, Dan Buettner (2008; 2012) identified other regions where similar patterns of longevity and low incidence of certain diseases, especially heart disease, cancer, and dementia, were observed. By overlaying the qualities associated with three of these special geographic areas: Okinawa, Japan; Sardinia; and the Seventh Day Adventist community of Loma Linda, California, Buettner identified features of the lifestyle that were common to all three:

Moderate daily activity as a regular aspect of life
A strong sense of life purpose
A low-stress, slower pace of life
Moderate calorie intake including a largely plant-based diet
Moderate alcohol consumption, especially red wine
Engagement in spirituality or religion
Engagement in family life
Engagement in social life with good friends

Building on the Blue Zone analysis, the Blue Zone Project is striving to adapt these features of a healthy, happy lifestyle to U.S. communities. They hope to introduce changes at the family, school, neighborhood, and health care levels in order to "make it easier to get up and move, eat healthy, make new friends, find a reason for being—and live longer, better" (Blue Zone Project, 2016). Currently eight cities/regions have embraced the Blue Zone guidelines to improve the health, community involvement, and well-being of their citizens.

Although the concept seems positive, there is also push-back and some scientific reservation about this idea. First, the population of isolated communities may spring from long-lived ancestors, thus ignoring the genetic basis to longevity among the residents. Second, adapting lifestyle characteristics from small isolated communities to modern towns may not be appropriate. Third, the Blue Zone characteristics identify features that are present, but not necessarily features that are absent from these lifestyles that may contribute to longevity, for example, lack of air pollution, traffic, noise, and other environmental features that create stress. Fourth, some critics view the Blue Zone guidelines as an imposition on their family privacy and a restriction of their personal freedoms. Finally, interviews with centenarians find quite a diversity of lifestyle features, suggesting that for the very long lived, there may not be one secret, or even one pattern of secrets (Murray, 2015).

The Gender Gap Among the Very Old

A discussion of aging in the United States must acknowledge the shifting sex composition of the population at older ages. In 2010, 60 percent of those 75 to 84 were women, 70 percent of those 85 to 94 were women, and 80 percent of those 95 and older were women (Werner, 2011). This **gender gap** in longevity is observed in virtually all countries of the world, but the differences are accentuated in the developed countries. The imbalance in the sex composition is much more noticeable today than it was 50 years ago when there were about as many men as women in the older-than-65 category. Because those currently at the stage of elderhood are predominantly women, many of the social issues of aging—especially poverty, health care, the future of Social Security, and housing—are also viewed as women's issues.

FURTHER REFLECTION: *The majority of the elderly are women. Generate some implications of this for social policy and community development.*

A New Psychosocial Stage: Elderhood

OBJECTIVE 1 Explain the rationale for identifying elderhood as a unique developmental stage for those of unusual longevity with its own developmental tasks and psychosocial crisis.

An increasing number of people are reaching advanced years and share certain personal and behavioral characteristics. This leads us to hypothesize a new stage of psychosocial development that emerges at the upper end of the life span after one has exceeded the life expectancy for one's birth cohort. This stage of life is experienced by the long-lived in a community who have outlived most of their age-mates. Drawing on the concept of village elders who share their wisdom and help resolve community disputes, we call this stage **elderhood**. Although it was not specifically identified in Erikson's original formulation of life stages, Erikson began to characterize the dynamics of psychosocial adaptation in this period of life in the book *Vital Involvement in Old Age* (Erikson et al., 1986). Throughout this chapter, we have drawn on Erikson's insights to enrich our appreciation of the courage, vitality, and transformations that accompany elderhood.

We have formulated a psychosocial analysis of development in elderhood based on research literature, firsthand reports, and personal observations to describe the developmental tasks, psychosocial crisis, central process, prime adaptive ego quality, and core pathology of this stage. We acknowledge that in many domains—especially physical functioning, reaction time, memories, and cognitive abilities—variability increases significantly with age. With advanced age, a person is less constrained by pressures of institutionalized roles and social demands. As a result, personal preferences and genetically based sources of individuality are freer to be expressed. In addition, individual differences reflect the diversity of educational experiences, health or illness, exposure to harsh conditions, and patterns of work and family life.

The concept of *norm of reaction* introduced in chapter 4 (The Period of Pregnancy and Prenatal Development) offers a framework for understanding the enormous variability in vitality and functioning during elderhood. The quality of functioning in elderhood is a product of the interaction among genetic factors, lifestyle choices, and environmental conditions. *Genetic factors* influence longevity, vulnerability to illnesses, intelligence, and personality factors that contribute to coping (Underwood, 2015).

ZUMA Press, Inc./Alamy Stock Photo

Former U.S. President Jimmy Carter continues to function in an informal role as a diplomat and advocate of peaceful solutions to world problems. Here he is at age 88. In 1982 he established the Carter Center, focusing on efforts to resolve conflict, promote democracy, protect human rights, and prevent disease. In 2002 he was awarded the Nobel Peace Prize.

Support for a genetic basis to longevity is provided from observations from the New England Centenarian Study that found that half the centenarians had grandparents, siblings, and other close relatives who also reached very advanced ages (Perls, Kunkel, & Puca, 2002; Sebastiani & Persl, 2012). An analysis of data from five studies of centenarians found that genetic profiles were increasingly accurate in predicting those who live to especially advanced ages—102 and beyond (Sebastiani et al., 2013).

Lifestyle factors include physical activity, diet, control over one's life, not smoking, moderate alcohol use, and the quality of one's social network. *Environmental conditions* that reduce longevity include poverty, discrimination, social alienation, and lack of social support. Data comparing the life expectancy across countries suggest that environmental conditions, including air and water quality, health care services, housing, and educational resources, all impact longevity beyond what the individual person can control (Katch, 2013).

Variations in life experiences and outlook among the very old are great. As a result, chronological age becomes less useful as an indicator of aging. Neugarten (1981) offered a distinction that helps clarify the functional differences among elders. She described two groups: the **old-old** and the **young-old**. The old-old have "suffered major physical or mental decrements," which increase their dependence on health and social services. This group will grow as the number of adults over 75 increases.

The majority of people over 75 can be described as young-old. They are competent, vigorous, and relatively healthy. They live in their own households and participate in activities in their communities. For example, among the New England centenarians studied, 90 percent were functionally independent and relatively healthy up until age 92 (Perls & Terry, 2007).

FURTHER REFLECTION: *Evaluate the argument that it is necessary to introduce a new stage of elderhood in the life-span perspective. What evidence supports the need to differentiate elderhood from the stage of later adulthood?*

Developmental Tasks

Despite the wide variability in capacities, lifestyles, and worldviews in later life, three themes characterize the challenges that face individuals in elderhood. First, they must adapt to *physical changes*, monitoring their health and modifying their lifestyles to accommodate these changes. Second, they must conceptualize their lives within a new *time frame*, realigning their thoughts about past, present, and future in order to stay connected to the present in a meaningful way. Third, they must develop new **life structures**—especially living arrangements and social relationships—that provide comfort, interest, and appropriate levels of care.

Coping with the Physical Changes of Aging

OBJECTIVE 2 List the physical changes associated with aging, and evaluate the challenges that these changes pose for continued psychosocial well-being.

There is no way to avoid the realization that with advanced age one's body is not what it used to be. Erikson described it as follows:

> With aging, as the overall tonus of the body begins to sag and innumerable inner parts call attention to themselves through their malfunction, the aging body is forced into a new sense of invalidness. Some problems may be fairly petty, like the almost inevitable appearance of wrinkles. Others are painful, debilitating, and shaming. Whatever the severity of these ailments, the elder is obliged to turn attention from more interesting aspects of life to the demanding requirements of the body. This can be frustrating and depressing. (Erikson et al., 1986, p. 309)

Aging, which is a continuous process over the life span, includes both development and decline. Some physical changes are considered to be normal or expected, and not especially related to disease. People who are well educated, have access to health care and other resources, and have observed healthy lifestyle practices in earlier stages of life are still going to experience some of the normative changes of aging when they reach advanced age, such as some loss of muscle strength or difficulty returning to normal respiration after periods of exertion. However, certain lifestyle practices including smoking cigarettes, alcohol and drug abuse, poor diet, and a sedentary life are likely to accelerate these patterns of normal decline. Other changes are disease related and not a result of normal aging. Genetic factors appear to increase vulnerability to these diseases, but so do lifestyle factors, exposure to toxins, and stress. Thus, we want to emphasize that the **physical changes of aging** are multidimensional and variable across individuals. Some people who have observed a healthy lifestyle in early and middle adulthood still experience diseases whereas others who have led a more risky lifestyle do not experience these diseases. We do not fully understand the extent to which genetic, environmental, social, and lifestyle factors help support continued health or vulnerability to disease in elderhood.

The theme of the physical changes of aging can be approached much like its counterpart in early adolescence. Although the rate of change may be slower, older adults notice changes in a range of areas, including appearance, body shape, strength and stamina, and the accumulation of chronic illnesses. Just as in adolescence, the rate and sequence of changes vary from person to person. The following sections identify major areas of physical change. Not all adults experience all of these changes, nor to the same degree. The level of fitness that was established and maintained during early and middle adulthood influence the progression of physical changes associated with aging. Important issues include the meaning that adults attribute to their physical condition and the coping strategies they invent to adapt to these changes. The topics of fitness, sleep and rest, behavioral slowing, sensory changes, health, illness, and functional independence combine to provide a picture of the physical changes of aging.

Fitness

There is a great deal of variation in **fitness** among people after age 75 as patterns of activity or inactivity, endurance or frailty, and illness or health take their toll. What is described here might be thought of as the usual patterns of aging. However, these changes are not inevitable and, in many instances, are reversible or modifiable with appropriate intervention (Dobek, White, & Gunter, 2007).

Seven components are often included in measures intended to assess fitness among the elderly: coordination, reaction time, balance, muscle strength, muscle endurance, flexibility, and cardiorespiratory endurance (Hilgenkamp, van Wijck, & Evenhuis, 2010). Among those 75 and older, elders who exhibit high levels of fitness are also likely to report a better overall quality of life, higher cognitive functioning, lower levels of depression, and a lower likelihood of encountering physical disabilities as they age (Tainaka, Takizawa, Katamoto, & Aoki, 2009; Takata et al., 2010; Voelker-Rehage, Godde, & Staudinger, 2010).

Most people begin to notice declines in their physical health and fitness in their late 20s and early 30s. As those who love baseball are likely to claim, "The legs are the first to go." On a more positive note, most people's strength and capacity for moderate effort are about the same at age 70 as they were at age 40 (Stevens-Long & Commons, 1992). However, older people are less resilient after a period of prolonged exertion. The respiratory and circulatory systems usually degenerate to some extent and are less capable of providing the heart and muscle tissue with oxygenated blood as quickly as they once could. One result is that sudden changes in posture can cause an older person to feel lightheaded. In order to adapt successfully to this kind of bodily change, an older person may find it necessary to move more slowly and to change positions more deliberately. This observable change in the tempo of movement may be incorrectly interpreted as fatigue or weakness when, in fact, it is often a purposeful strategy for preventing dizziness.

Nutrition and Fitness.

Slowed metabolism reduces the need for calories, but there are new risks. Blood sugar levels are likely to rise after eating and body fat increases. These conditions increase the risk of type 2 diabetes. Reduction in food intake—particularly the elimination of foods such as milk—may result in the lack of essential vitamins and minerals in an older person's diet. The resulting malnutrition may then contribute to osteoporosis and iron deficiencies, which produce feelings of weakness, fatigue, and a lack of resilience (Klesges et al., 2001). In order to cope successfully with a diminished appetite, elders must become more conscientious in selecting foods that will provide the nutritional elements necessary for healthy functioning.

Many health concerns of later adulthood that may have been attributed to the aging process itself are in fact a direct or indirect result of malnutrition. In the years from 2007 to 2009, a period of severe economic downturn in the United States, researchers reported substantial increases in food insecurity among adults including those in middle and later adulthood as well as elderhood (Ziliak & Gunderson, 2011). Food insecurity is associated with lower nutritional intake, fewer calories, less protein, fewer essential vitamins, greater likelihood of reporting poor or fair health, and significant increases in functional limitations, requiring assistance in activities of daily living (Lee & Frongillo, 2001). There is speculation that adults who suffered from food insecurity in their middle and later adult years may reach elderhood in a state of greater frailty and in need of more health services.

Lifestyle and Fitness.

A number of factors make it difficult to maintain a high level of physical fitness in later life. Some aspects of aging that impact fitness are a result of the body's natural process as cells replicate again and again and, through metabolism, produce by-products that can be harmful to the body itself. Some aspects of aging that reduce fitness are a result of choices and circumstances such as a sedentary lifestyle, smoking, a diet heavy in fats, too much time in the sun, exposure to environmental toxins, and lack of health care.

Commitment to physical fitness is important for adults in order to face their later years in the best possible physical condition. In its report *Healthy People 2020*, the U.S. government identified physical activity as a key factor in promoting health and

Those who survive into their 90s demonstrate surprising good health. Solly has been bowling since he was 10; at age 96, he still enjoys the sport and carries a 123 average in the 80 and older league.

preventing illness (U.S. Department of Health and Human Services, 2013). A primary goal is to improve health, function, and quality of life for older adults. Among the recommendations to achieve this goal is to encourage regular, daily physical activity. The recommended level of physical activities includes 2 hours and 30 minutes a week of moderate aerobic activity, strengthening activities 2 days a week, and balancing activities 3 days or more a week.

Regular physical activity is associated with decreased rates of death from heart disease, lower risk of diabetes and colon cancer, and prevention of high blood pressure. Physical activity also improves muscle and bone strength, contributes to weight control, and improves strength, flexibility, and balance. These latter factors all reduce chances of serious injury, thereby preserving functional independence. Despite these advantages, only 27.6 percent of people ages 75 and older meet the guidelines for aerobic activity, and 9 percent meet the combined guidelines for aerobic and strengthening (National Center for Health Statistics, 2016b).

With advancing age, some people tend to become more sedentary and lose interest in physical activity. In order to maintain optimal functioning and to retard the degenerative effects of aging, very old adults must continue to have frequent and regular opportunities for physical exercise. A regular program of walking or other aerobic exercise can enhance cardiovascular functioning and reverse some of the effects of a sedentary adult lifestyle, resulting in both improved mood, increased reaction time, and improved performance on tests of working memory (Hogan, Mata, & Carstensen, 2013). Research on weight, or resistance, training shows that even among the very old, a steady program of exercise builds muscle strength, which contributes to agility and an overall sense of well-being (Ades, Ballor, Ashikaga, Utton, & Nair, 1996; Seguin, Epping, Buchner, Bloch, & Nelson, 2002). Weight-bearing exercises help offset the normal processes of loss of muscle tone and bone density, improving balance and reducing the likelihood of falls. Experimental studies of the effects of exercise on cognitive functioning show that it also leads to improvements in various central nervous system functions. These benefits of exercise are attributed in part to higher levels of oxygen that improve the metabolism of glucose and neurotransmitters in the brain, as well as to increased levels of arousal that increase response speed (Newell, Vaillancourt, & Sosnoff, 2006).

Sleep and Rest

Older adults seem to need about 7 to 9 hours of sleep a night. However, older adults tend to go to sleep earlier and wake up earlier than when they were younger and spend less time in deep sleep, which may be why older adults often report being light sleepers (National Institute on Aging, 2016). Sleep problems, including difficulty falling asleep, periods of wakefulness after falling asleep, and shorter length of sleep are often observed among the elderly, even among older adults who say their quality of sleep is fine (Cavuoto et al., 2016). These sleep problems are associated with poorer performance on memory tasks and poor consolidation of newly learned information, especially tasks requiring visual and motor coordination (Mantua, Bran, & Spencer, 2016). More significant sleep problems occur for older adults who have various medical conditions that involve pain, sleep apnea, movement disorders, and urinary problems. In a large sample of elderly women, those who suffered from arthritis and heart disease also reported the greatest sleep difficulties (Leigh, Hudson, & Byles, 2016; Ohayon, Carskadon, Guilleminault, & Vitiello, 2004).

The most common sleep problem in elderhood is *insomnia*, which involves difficulties falling asleep or staying asleep. Insomnia may be a temporary problem associated with particular worries, excitement over an upcoming event, or preoccupation with an unresolved challenge. On the other hand, insomnia may be a symptom of other medical conditions, such as unmanaged pain or difficulty breathing. People who have had a bout of insomnia may exacerbate their problem by worrying about whether they will be able to fall asleep (National Institute on Aging, 2016).

> Ever since he retired, Edward dreads going to bed at night. He's afraid that when he turns off his light, he will just lie there with his eyes open and his mind racing. "How can I break this cycle?" he asks. "I'm so tired—I need to get some sleep." (National Institute on Aging, 2016)

Problems with sleep may also lead to subsequent difficulties in cognition and a sense of well-being. Given the role of sleep for supporting memory, consolidation of new learning, and positive mood, older adults who have sleep difficulties may also be at greater risk for depression, declines in cognitive functioning, and disease. One analysis of five longitudinal studies found that insomnia was a significant predictor of subsequent risk of dementia (de Almondes, Costa, Malloy-Diniz, & Diniz, 2016; Leigh, Hudson, & Byles, 2016).

Many older adults take daytime naps; an estimated 15 percent of those ages 55 to 64 and 25 percent of those ages 75 to 84 nap. There may be benefits from the practice of napping. In a study that tracked over 23,000 Greek adults for 6 years, those who napped three times a week or more for about half an hour had a substantially lower risk of heart attacks than those who did not nap (Naska et al., 2007). Napping has also been associated with improved memory consolidation among the elderly, especially for visual memories (Ladenbauer et al., 2016). Napping may help reduce stress and allow a person to engage the remainder of the day with more energy. In a study of napping among older adults, those who had a regular habit of sleeping at about the same time each day and waking themselves up after about half an hour had a greater sense of self-efficacy and less experience of sluggishness in the afternoon and evening (Kaida et al., 2006).

Several hypotheses link napping to well-being. People who are able to nap during the day may also be in greater control of their lives and less exposed to stress. Taking a nap may be a deliberate way to reduce stress, relax, and prepare to engage more fully in the remaining hours of the day. Cognitive benefits of a nap may contribute to feelings of well-being. Despite the benefits of a brief nap, when a person is napping several times a day this may be linked to unusual feelings of sleepiness, depression, and pain, which may indicate a more serious health problem (Foley et al., 2007).

Behavioral Slowing

One of the most commonly noted markers of aging is a gradual slowing in response to stimuli. **Behavioral slowing** is observed in motor responses, reaction time, problem-solving abilities, memory skills, and information processing (Salthouse, 1996). Reaction time is a composite outcome of the time it takes to perceive a stimulus, retrieve related information from memory, integrate it with other relevant stored information, reason as necessary about the required action, and then take action—whether that means the time it takes to press a button after detecting a signal, or the time it takes to complete a crossword puzzle or solve a math problem. Age-related slowing is more readily observable in complex tasks requiring mental processing than in routine tasks (Lemaire, Arnaud, & Lecacheur, 2004). The more complex the task, the greater the **processing load**—that is, the more domains of information called into play, the more time it takes to select response strategies.

The number of tasks presented in a sequence and the complexity of choice required to make a response are all factors that influence response time. Under conditions where a choice of response is required, older adults do not show evidence of slowing in the early phase of processing the stimuli, but in the executive functions associated with enacting the appropriate response (Yordanova, Kolev, Hohnsbein, & Falkenstein, 2004). In many studies, older adults show improvements in response time when given opportunity for practice. However, when older and younger adults are both given opportunities for practice, the older adults do not improve as much as the younger adults, and the performance gap may actually increase (Hein & Schubert, 2004).

Biological, learned, and motivational factors may account for behavioral slowing. At the biological level, there is evidence of the slowing of neural firing in certain brain areas, which may result in a slower speed of information processing. This is due in part to age-related damage to the myelin sheath that insulates neurons and facilitates speed of firing (Salat, 2011). The extent of this slowing depends on the kinds of tasks and specific cognitive processes involved. Speed of processing may be only one of many factors responsible for age-related changes in cognitive processing (Hartley, 2006). Older adults appear to be effective in recruiting various brain regions to compensate for declines in processing speed, which stimulates new patterns of connections across the hemispheres of the brain. Research on brain functioning in later life finds evidence for plasticity and adaptive reorganization (Davis, Kragel, Madden, & Cabeza, 2012).

The slowing of responses may also be a product of learned cautiousness. With experience, people learn to respond slowly in order to avoid making mistakes. When confronted with new, experimental problem-solving tasks, older adults may take longer because they are not confident in using a new strategy. They may revert to a more familiar, if more time-consuming, approach in order to solve the problem correctly. Thus, a conservative orientation to the selection of problem-solving strategies may result in slower responses but not be strictly due to neurological causes (Touron & Hertzog, 2004). Depending upon the task, cautiousness may be related to prior experiences of instability or falling. As older adults step down from the sidewalk to the street, or step off an elevator or onto an escalator, they move more slowly to ensure that they have good footing and will not slip or fall. Finally, response slowing may be a product of a low level of motivation to perform a task. In experiments in which reaction time is being tested, adult participants may be uninterested in the task and thus unwilling to try to respond quickly.

The implications of the consequences of behavioral slowing are currently being examined. Some researchers argue that even the slightest reduction in the speed of neural firing may result in reduced sensory and information-processing capacities. Furthermore, response slowing may reduce a person's chances of survival if a situation arises in which a sudden evasive action or immediate response is required. Others have suggested that if a moment of thought is required before an action is taken, slowness may increase a person's chances of survival.

The impact of slowing on cognitive functioning continues to be debated. If the nervous system functions at a slower rate, it takes more time to scan and perceive information, search long-term memory, integrate information from various knowledge domains, and make a response (Madden, 2001). However, mental abilities that rely on speed, which are often assessed under laboratory conditions, do not predict cognitive functioning for elders in their real-world environments. Although it is well established that speed of performance declines with age, there are few real-world situations that require the rapid speed that is typically measured in laboratory conditions. As they age, people typically create living conditions that are adapted to their abilities, allowing them to preserve effective problem-solving strategies as well as possible (Salthouse, 2012). Recall from chapter 13 (Later Adulthood) that crystallized intelligence tends to increase with age, whereas fluid intelligence declines. When the factor of speed of responding was removed from the tests of fluid intelligence, the decline with age was significantly less. Contemporary circumstances—especially physical fitness and health, as well as the kinds of medications one is taking and the presence of immediate stressors in one's life—influence the speed of responding. In each situation, motor performance results from the adaptive self-organization of responses that are a product of how the person assesses the situation; the person's physical strength, flexibility, and endurance; and the person's ability to control posture, movement, and dexterity. Speed of responding will vary depending on what type of response is required and which systems constrain behavior (Newell, Vaillancourt, & Sosnoff, 2006). One 80-year-old woman may be able to walk through an airport quickly to get to her gate but may be slow in reading and evaluating the information that tells whether her flight is on time or delayed. Another 80-year-old woman may be able to read the information about the flight and quickly assess whether her flight is on time but may take much longer to get to the departure gate.

Because slowing occurs gradually, most adults compensate for it by making their environments more convenient or by changing their lifestyles. However, slowing becomes more hazardous in situations that require the older adult to keep pace with a tempo that cannot be modified, such as highway driving or crossing the street with the light. For instance, some older people encounter problems because the amount of time the light stays green at a pedestrian crosswalk is insufficient to permit them to get to the other side of the street safely. Elders may become more selective in their choice of activities so that they can allocate enough time for the tasks most important to them and perform them satisfactorily. This means exercising greater control over their time and being less concerned about whether they are in harmony with the tempo of others.

Noel Hendrickson/Jupiter Images

As a result of behavioral slowing, it takes longer for elders to perform daily tasks. Her trips to the market take May more time than they did 10 years ago, but she still enjoys her shopping and the satisfaction of preparing her meals with the best ingredients.

Sensory Changes

The story of sensory development began in our discussion of fetal development (chapter 4). The term "sensorimotor intelligence" reflects the key role that the sensory system plays in supporting cognition, from infancy and beyond. From an evolutionary perspective, the sensory capacities are vital for survival, providing information about threats, decay, and dangers. The sensory system also supports experiences of comfort, beauty, joy, and transcendence.

Every sense modality—vision, hearing, taste, touch, and smell—is vulnerable to age-related changes. With age, greater intensity of stimulation is required to make the same impact on the sensory system that was once achieved with lower levels of stimulation. Some of the changes in vision, hearing, and taste and smell are listed in Table 14.1. These changes begin in early adulthood, and their effects increase throughout the remainder of life

Table 14.1 Changes in Sensory Systems After Age 20

Age Group	Vision	Hearing	Taste and Smell
20–35	Constant decline in accommodation as lenses begin to harden at about age 20	Pitch discrimination for high-frequency tones begins to decline	No documented changes
35–65	Sharp decline in acuity after 40; delayed adjustment to shifts in light and dark	Continued gradual loss in pitch discrimination to age 50	Loss of taste buds begins
65+	Sensitivity to glare; increased problems with daily visual tasks; increases in diseases of the eye that produce partial or total blindness	Sharp loss in pitch discrimination after 70; sound must be more intense to be heard	Higher thresholds for detecting sour, salt, and bitter tastes; higher threshold for detecting smells, and errors in identifying odors

Source: Based on Newman & Newman, 1983.

(Erber, 2005). Results from a large, national sample of adults aged 57 to 85 found that roughly two thirds of the respondents experienced a significant deficit in at least one sense, and that the incidence of multiple sensory deficits increased with age. Among the oldest participants, difficulties in hearing, vision, and smell were more prominent (Correia et al., 2016). About 20 percent of those ages 75 and older have multiple sensory impairments. Those who have both visual and hearing impairments are more likely to report reduced social interactions, difficulty getting together with friends, and are at greater risk for falls, possibly due to the lack of sensory cues that help support navigation in unfamiliar settings (He et al., 2005).

Vision. **Visual adaptation** involves the ability to adjust to changes in the level of illumination. Pupil size decreases with age, so that less light reaches the retina. Thus, older adults need higher levels of illumination to see clearly, and it takes them longer to adjust from dark to light and from light to dark. Many older adults are increasingly sensitive to glare and may draw the shades in their rooms to prevent bright light from striking their eyes. Slower adaptation time and sensitivity to glare interfere with night driving. Some of the visual problems of people older than 75 are difficulties with tasks that require speed of visual performance, such as reading signs in a moving vehicle; a decline in near vision, which interferes with reading and daily tasks; and difficulties in searching for or tracking visual information (National Institute on Aging, 2009a). About 16.5 percent of those 75 and older report that they have trouble seeing (National Center for Health Statistics, 2010).

Several physiological conditions seriously impair vision and can result in partial or total blindness. These conditions include cataracts, which are a clouding of the lenses, making them less penetrable by light; deterioration or detachment of the retina including age-related macular degeneration, which can result in blurring details needed for sewing, reading, and driving or complete vision loss; corneal disease, which can result in redness, watery eyes, pain, and difficulties seeing; and glaucoma, which is an increase in pressure from the fluid in the eyeball. The incidence of visual impairments, especially cataracts, increases dramatically from later adulthood (65 to 74) to elderhood (beyond 75) (He, Sengupta, Velkoff, & Barros, 2005; National Institute of Health, 2016).

By age 75, half of Anglo Americans have cataracts or have had them removed. By age 80, 70 percent of Anglo Americans have cataracts compared with 53 percent of African Americans and 61 percent of Hispanic Americans (National Eye Institute, 2016). According to vision experts, recent medical innovations have made cataract surgery much less complicated than it was in the past. Nine out of 10 people who have cataract surgery regain very good vision, somewhere between 20/40 and 20/20 (Lee, 2002).

Loss of vision poses serious challenges to adaptation—it has the effect of separating people from contact with the world. Such impairment is especially linked with feelings of helplessness. Most older adults are not ready to cope with the challenge of learning to function in their daily world without being able to see. For them, the loss of vision reduces their activity level, autonomy, and willingness to leave a familiar setting. For many older adults, impaired vision results in the decision to give up driving altogether, or at least night driving, causing a significant loss of independence. However, this loss can be minimized by the availability of inexpensive, flexible public transportation.

Hearing. Hearing loss increases with age. About 47 percent of those ages 75 and older have some trouble with their hearing (National Institute of Health, 2016). The most common effects of hearing loss are a reduced sensitivity to both high-frequency (high-pitched) and low-intensity (quiet) sounds and a somewhat decreased ability to understand spoken messages. Tinnitus, a ringing or buzzing sound that can come and go, and appear to be loud or soft, often accompanies other forms of hearing loss or as a side effect of certain medications. Certain environmental factors—including exposure to loud, unpredictable noise, and injuries, such as damage to the bones in the middle ear—influence the extent of hearing loss.

Loss of hearing interferes with a basic mode of human connectedness—the ability to participate in conversation. Hearing impairment may be linked to feelings of isolation or suspiciousness. A person may hear things imperfectly, miss parts of conversations, or perceive conversations as occurring in whispers rather than in ordinary tones. There are a variety of devices that can help support individuals who have hearing loss. These include hearing aids, amplifying devices that can make it easier to hear on the phone, alert systems coordinated with doorbells or smoke detectors, and cochlear implants that are surgically implanted to help overcome certain specific types of hearing loss (National Institute on Aging, 2009b).

Being aware of one's hearing loss and its impact on social interactions is the first step in learning to compensate for diminished auditory sensitivity. Knowing the people one is with and believing that one is valued by them can help reassure a person about the nature of conversations and allay suspicions. Elders with hearing loss may ask for a quiet spot in a restaurant or ask friends to speak one at a time in a group setting. Self-esteem plays an important part in this process. An older person with high self-esteem is more likely to make the intellectual adjustment needed to interpret interactions and to request clarification when necessary. Such requests may even serve to stimulate greater interaction and produce greater clarity in communication. Older people with a hearing loss and high self-esteem tend to insist that people who want to communicate with them should face them when they speak.

In contrast, older people who have low self-esteem are likely to be more vulnerable to suspicions about the behavior of others. They are more likely to perceive inaudible comments as attempts to ridicule or exclude them. These experiences contribute to feelings of rejection and can produce irritability and social withdrawal.

Taste and Smell. There are taste receptors throughout the mouth, including on your tongue, the roof of your mouth, and your throat. These receptors detect flavors of food based on five tastes: sweet, salty, bitter, sour, and tangy. In addition, the smell of food contributes to its flavor, and many would argue that the

Irina Afonskaya/Shutterstock.com

The sense of smell invigorates daily experiences and continues to be a source of pleasant memories. Greta smells the lilacs, a delightful sign that spring has come. She remembers gathering lilacs as a gift for her mother on Mother's Day.

appearance of food contributes to its appeal. With age, the number of taste buds decreases. Older adults have a higher threshold than young adults for detecting sweet, sour, bitter, and salty tastes. Some of this reduced sensitivity may be related to the impact of certain medications, gum disease, dentures, some infections, cancer treatments, or alcohol consumption (National Institute on Aging, 2009c). In order to improve the taste of food, older adults may add salt or sugar, which may aggravate existing conditions such as high blood pressure or diabetes. An impaired sense of taste can interfere with the ability to detect spoiled foods or ingredients that are likely to cause indigestion.

Smell and taste are closely linked. Much of the flavor that we experience from foods comes from its aroma. Deficits in the sensory capacity for smell occur in about 22 percent of adults, with problems increasing with age (Correia et al., 2016). Older adults may require greater intensity to detect odors and are more likely to misidentify them. Loss or change in the sense of smell can be a symptom of other diseases. The sense of smell can keep a person safe. Smells related to smoke, gas leaks, spoiled food, or household chemicals are important indications of a possible environmental problem. Loss of smell in older adults can increase their vulnerability to illness or accidents. Changes in the senses of smell and taste may result in a loss of appetite or a disruption of normal eating habits. Loss of appetite (which may accompany illness and new medications), pain due to dental problems, and changes in the digestive system all contribute to malnutrition among the elderly.

Coping with Sensory Changes

As a result of the various patterns of aging among the very old, it is impossible to prescribe an ideal pattern of coping with sensory changes. The first step is awareness. Elders need to be aware that changes in sensory systems are likely and pay attention to these changes, especially reductions in sensitivity that might impact their safety and health. The second step is evaluation. Most annual check-ups do not focus on the full sensory systems. If a person has diabetes, or a history of diabetes, annual eye exams are customary. However, problems in other sensory systems may not be included in an annual exam unless a person indicates a problem. Elders need to check with their physician about possible side effects of their medications that might impact the sense of smell, taste, touch, vision, or hearing. The third step is intervention. In some cases, a sensory deficit can be improved through medications or devices (e.g., eyeglasses or hearing aids). If deficits are not reversible, new coping strategies can be implemented that compensate for the loss of certain sensory stimuli. Guided by the SOC model, older adults must select the areas where they are most invested in sustaining optimal functioning and direct their resources to enhancing those areas while compensating for the areas in which functioning is more limited. What one hopes to achieve is a balance between self-sufficiency and willingness to accept help, preserving one's dignity as much as possible and optimizing the enjoyment of daily experiences.

Health, Illness, Disability, and Functional Independence

How can we characterize the level of health, illness, disability, and **functional independence** in later life? A mild but persistent decline in the immune system is observed as a correlate of aging. As a result, older adults are more susceptible to infections and take a longer time to heal. Substantial numbers of older adults are afflicted with one or more chronic conditions, such as arthritis, osteoporosis, diabetes, or high blood pressure, which may require medication and interfere with daily functioning. Older adults are at increased risk for developing chronic conditions, the most common of which are diabetes, arthritis, congestive heart failure, and dementia (U.S. Department of Health and Human Service, 2013). Nonetheless, 39 percent of those aged 75 and older describe their health as very good or excellent, and 35 percent report their health as good (Schiller, Lucas, Ward, & Peregoy, 2012).

Disability. What is disability? Some diseases result in impairments in organs; others result in limitations in physical or mental functioning. Functional limitations are typically measured by asking about specific tasks like walking up a flight of stairs or driving a car. Some functional limitations are significant for carrying out tasks of daily life, like preparing food, showering/bathing, or getting dressed. Other limitations may only be relevant for certain people, depending on the work they do, where they live, or their family responsibilities. The term **dependence** refers to health-related limitations that impact a person's ability for independent life including self-care and more complex tasks like shopping or using the phone. Two indicators of disability in later life are whether a person needs assistance with basic activities of daily life (ADLs), including eating, bathing, dressing, and moving from the bed to a chair or to the bathroom, and **instrumental activities of daily life (IADLs)** including light housework, grocery shopping, or preparing meals. Depending on how it is measured, the term

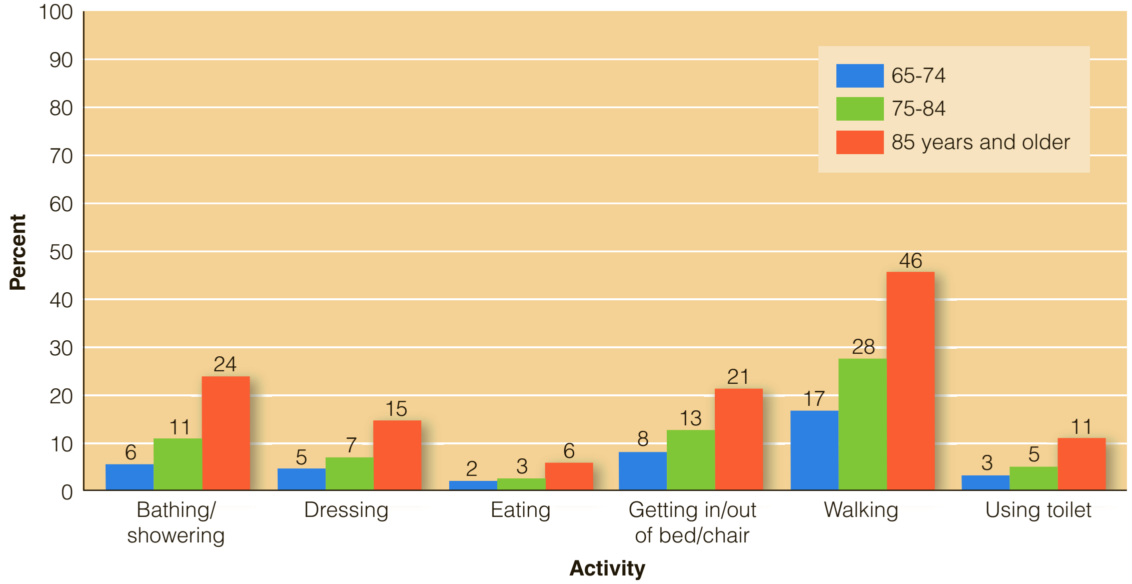

FIGURE 14.1 ▶ PERCENT OF PERSONS WITH LIMITATIONS IN ACTIVITIES OF DAILY LIVING BY AGE GROUP: 2010

Source: Administration on Aging (2012).

disability can include functional limitations and/or dependence (Cutler, 2001).

In contrast to negative stereotypes about later life, the level of independent functioning among adults 80 years and older is high. FIGURE 14.1 ▶ shows the percentages of noninstitutionalized people in three age groups who needed help in six **activities of daily living (ADLs)**: bathing/showering, dressing, eating, getting in and out of bed or a chair, walking, and using the toilet. The area of greatest limitation is walking. The percentage of adults needing assistance is small for those ages 65 to 74, increases slightly for those 75 to 84, and increases further for those 85 and older. However, even among this oldest group, fewer than half require help with walking, and fewer than 25 percent need help with other basic tasks of self-care (Administration on Aging, 2012).

From 1992 to 2013, the percentage of people aged 65 and older who report having ADLs or IADLs has *decreased* from 48.9 percent to 44 percent (Federal Interagency Forum on Aging-Related Statistics, 2016). Many factors account for this improvement in daily functioning for recent cohorts including improved education of recent elders, fewer people smoking, improved design of interior spaces in senior housing, new devices that make it easier for older adults to compensate for physical limitations, and medications that help alleviate the symptoms of chronic illness. Improved treatment of cataracts and heart disease are especially important contributors to this reduction in disability (Chernew, Cutler, Ghosh, & Landrum, 2016).

Osteoarthritis is the most common type of arthritis for older adults. This type of arthritis results when the cartilage that pads bones in a joint wears away. The joints may feel stiff when a person has not moved for a while. Other symptoms include temporary or chronic pain and gradual loss of mobility in the affected joints. Fifty-four percent of those 75 and older have osteoarthritis. *Osteoporosis* is a disease that weakens bones so that they break easily. Bone tissue is continuously broken down and replaced. With age, more bone is lost than is replaced. Although women are at greater risk of osteoporosis than men, after age 70 men and women lose bone at about the same rate (National Institute on Aging, 2009d, 2009e).

Data from the National Health Interview Survey (Schiller, Lucas, Ward, & Peregoy, 2012) provide a look at the relationship of age to difficulties in physical functioning. Participants were asked about whether they had certain upper-body and lower-body limitations. Upper-body limitations included such things as reaching up over one's head or using one's fingers to grasp a handle. Lower-body limitations included walking for a quarter mile or stooping, crouching, or kneeling. The percentage of respondents who reported difficulty in one or more areas increased from 30 percent of those ages 65 to 74, to 46 percent among those 75 and older. The area of most difficulty was standing for 2 hours, with 30 percent of those over age 75 reporting difficulties. This suggests that many elders would not go to an outdoor concert without bringing a chair.

One of the most difficult health challenges of elderhood is a group of disorders referred to as **organic brain syndromes**. These conditions, which result in confusion, disorientation, and loss of control over basic daily functions, present obstacles for adaptation to the person with the disease as well as the caregivers who are responsible for the older person's well-being (see the **Applying Theory and Research** box Dementia).

Do people generally experience a rapid, general decline in health after age 65 or 70? Not according to self-ratings. In a national survey of older adults, people were asked to rate their health from poor to excellent. In the 75 to 84 age range, 76 percent of non-Hispanic Whites, 57 percent of non-Hispanic Blacks, and 60 percent of Hispanics rated their health as good, very good, or excellent. Among those 85 and older, the percentage who rated their health as good, very good, or excellent declined somewhat for the three groups, to 69 percent, 55 percent, and 52 percent,

APPLYING THEORY AND RESEARCH TO LIFE

Dementia

Dementia is the loss of thinking, memory, and reasoning skills that significantly impairs a person's ability to carry out daily tasks. Symptoms include the inability to remember information, asking the same questions over and over again, becoming lost or confused in familiar places, being unable to follow directions, or neglecting personal safety, hygiene, or nutrition (National Institute on Aging, 2009f). Two of the most common causes of dementia in older people are vascular dementia or repeated small strokes and Alzheimer's disease. With **vascular dementia**, the supply of blood to the brain is disrupted, resulting in the death of brain cells. The loss of function may be gradual or relatively sudden. The symptoms vary depending upon which area of the brain has been damaged. Memory, language, reasoning, or motor coordination can be disrupted. Supportive counseling, attention to diet, and skilled physical therapy to reestablish control of daily functions may restore much of the person's previous level of adaptive behavior provided that additional strokes do not occur.

Alzheimer's disease produces a more gradual loss of memory, reduced intellectual functioning, and an increase of mood disturbances—especially hostility and depression. An estimated 5.4 million Americans had Alzheimer's disease in 2012. The incidence of this disease increases with age, with few people below the age of 60 affected by it, whereas an estimated 45 percent of those ages 85 and older have the diagnosis. The severity of the disease also increases with age (Alzheimer's Association, 2013).

A person with Alzheimer's disease experiences gradual brain failure over a period of 7 to 10 years. Symptoms include severe problems in cognitive functioning, especially increased memory impairment and a rapid decline in the complexity of written and spoken language; problems with self-care; and behavioral problems, such as wandering, asking the same questions repeatedly, and becoming suddenly angry or stubborn (Kemper, Thompson, & Marquis, 2001; O'Leary, Haley, & Paul, 1993). Currently, there is no cure for Alzheimer's disease. Treatments address specific symptoms—especially mood and memory problems—and attempt to slow its progress.

As the number of older adults with Alzheimer's disease and related disorders has grown, the plight of their caregivers has aroused concern (Roth et al., 2001; Zarit, Femia, Kim, & Whitlatch, 2010). Most Alzheimer's patients are cared for at home, often by their adult children and their spouse. The caregiving process is ongoing, with an accumulation of stressors and periodic transitions as the patient's condition changes. As the symptoms of the disease progress, caregivers have to restructure their personal, work, and family life. Caregivers often experience stress and depression as they attempt to cope with their responsibilities and assess the effectiveness or ineffectiveness of their efforts. Over time, they are likely to experience physical symptoms of their own, associated with the physical and emotional strains of this role.

When people with dementia are cared for at home by their spouse, children, or other relatives, three spheres of functioning intersect: home life, intimate or close relationships, and custodial care. Custodial care often involves routinization, surveillance, and indignities as a result of lost capacities, such as needing help with toileting, bathing, or dressing. Observations and interviews with caregivers and care recipients who live together suggest that these features of custodial care disrupt intimate relationships and home life, making daily experiences more monotonous, restrictive, and constraining. As their symptoms worsen, care recipients gradually lose many of the functions that support their identities as homemakers, parents, or intimate partners (Askham, Briggs, Norman, & Redfern, 2007).

The care of an older person with some form of dementia is fraught with problems and frustrations, but it also provides some opportunities for satisfaction and feelings of encouragement (Pinquart & Sörensen, 2003). The uplifts and hassles frequently reported by caregivers give some insight into the typical day-to-day experience of caring for a person who is suffering from Alzheimer's disease (Donovan & Corcoran, 2010; Kinney & Stephens, 1989).

The uplifts include the following:

- Seeing care recipient calm
- Sharing a joke, laughing together with the care recipient
- Seeing care recipient responsive
- Care recipient showing affection
- Friends and family showing understanding about caregiving
- Care recipient recognizing familiar people, smiling, or winking
- Care recipient being cooperative
- Leaving care recipients with others at home

Some of the hassles include:

- Care recipient being confused or not making sense
- Care recipient's forgetfulness, asking repetitive questions
- Care recipient's agitation, anger, or refusing help
- Care recipient's bowel or bladder accidents
- Seeing care recipient withdrawn or unresponsive
- Dressing and bathing care recipient, assisting with toileting
- Care recipient declining physically
- Care recipient not sleeping through the night

Two symptoms that are most difficult to manage are sleep disturbances and wandering. As cognitive functioning declines, the pattern of sleep deteriorates. A person with Alzheimer's disease sleeps for only short periods, napping on and off during the day and night. Often, the napping is accompanied by wakeful periods at night, during which the person is confused, upset, and likely to wander. Caregivers must therefore be continuously alert, night and day. Their own sleep is disturbed as they try to remain alert to the person's whereabouts. When the disease reaches this level, family caregivers are likely to institutionalize the family member. Alzheimer's disease is a major cause of hospitalization and nursing home placement among the elderly; an estimated 50 percent of nursing home residents have Alzheimer's disease or a related form of dementia (He, Sengupta, Velkoff, & DeBarros, 2005).

A woman who remembers her mother as independent, with strong views and a deep commitment to social justice, describes some of the ups and downs as she witnesses her mother's condition:

> My mother also had strong views on quality of life issues for the elderly. We had often spoken about the importance of being able to die in a dignified way. She has a living will and opposes heroic measures to prolong life. I am convinced that Mom wouldn't want the quality of life she now has. She can't express herself, is unable to hold a knife or fork, has no control over her bodily functions and can't walk.

However, on a recent visit to her mother, who is living in a group home, she describes the following scene:

> I worried. . . . that Mom wouldn't recognize me this time. But when I got there, she looked up at me and broke into a huge smile. She was truly excited to see me. She laughed and as I hugged her, we both cried. Then she began to speak nonstop gibberish. Although she can't tell us otherwise, my mother appears to be happy. . . . I honestly don't know if she has any thoughts about quality of life. (Simon, 2002, p. B7)

Critical Thinking Questions

1. Imagine that you are responsible for the care of a loved one who has Alzheimer's disease. What steps could you take to help support their optimal functioning?
2. Hypothesize about psychosocial development for adult caregivers. How might the responsibilities of care contribute to or impede their psychosocial development?
3. Explain why sleep disturbances and wandering are the symptoms that are most likely to lead to institutionalization for those with Alzheimer's disease.
4. Hypothesize about why an adult child may want to care for a parent who has Alzheimer's disease rather than place him or her in a nursing home or extended care facility.
5. Imagine being responsible for someone with dementia. Describe how you would prepare for this role. How would you plan for the long-term nature of this responsibility and cope with the continuing deterioration of your loved one?

respectively (Federal Interagency Forum on Aging Related Statistics, 2012). However, the majority continue to view their health in a positive light.

Among those in their 80s and early 90s, one health-related crisis may result in a marked decline in other areas. For example, the loss of a spouse may result in social withdrawal, loss of appetite, sleep disturbance, loss of energy, unwillingness to take medication, and decline in physical activity. All these changes can produce a rapid deterioration of the respiratory, circulatory, and metabolic systems.

People in their late 90s and older demonstrate unexpectedly good health. They appear to be more disease free than those who are 10 or 15 years younger. Perls (2004) suggested that a combination of genetic factors protect some people from the diseases of aging through two complementary processes. First, they are less vulnerable to some of the damaging effects of *oxygen radicals* that destroy DNA and cells. Thus, during their 70s and 80s, they do not suffer from the major diseases such as heart disease, cancer, stroke, or Alzheimer's disease. Second, they have a greater *functional reserve*, meaning that they require less of their organs to perform basic adaptive functions so they can tolerate a degree of damage without losing basic capacities. Studies of centenarians confirm this view of aging; they typically have a short period of poor health before death rather than suffering from prolonged disease-torn illness and disability.

FURTHER REFLECTION: *Describe someone you know well who is in the life stage of elderhood. What physical challenges is this person facing? How is he or she coping with these challenges? What environmental and/or social supports are required to help sustain this person's optimal functioning?*

Developing a Psychohistorical Perspective

OBJECTIVE 3 Describe the concept of a psychohistorical perspective, an altered outlook on time and history that emerges among the long-lived.

A psychohistorical perspective, achieved in elderhood, is the product of an integration of past, present, and future. Through a process of creative coping, elders in each generation blend the ideas, experiences, and salient events of their past histories with the contexts of current reality. Elders reach new levels of conscious thought. They are more aware of alternatives; they can look deeply into both the past and the future and can recognize that opposing forces can exist side by side (Kunzmann & Baltes, 2005; Riegel, 1973). In a rapidly changing society, elders may be perplexed by the emergence of new technologies, new social norms, and new products. At the same time, they have seen a history of change and recognize the enduring values and qualities of a good life in the midst of change. Having lived a long time, and envisioning less time in the future, elders are more likely to be more forgiving, less interested in material accumulation, and more focused on the emotional satisfactions of life (Allemand, 2008; Brandtstädter, Rothermund, Kranz, & Kühn, 2010). The idea of a *psycho*historical perspective suggests that people will differ in the meanings and interpretations they give to the events of their lives. Nonetheless all elders have to face the inevitability of change and strive to create a meaningful narrative around the decisions and directions of their life in the context of change.

Bill Aron/PhotoEdit

Wendell tells his young listeners what it was like to be a soldier in World War II. Through his stories, he makes this period of American history come alive for a new generation.

Think about what it means to have lived for 75 or more years. Those adults who were 85 years old in 2016 were born in the Great Depression. They are members of the silent generation. They lived through World War II but were too young to serve; the Korean war; the Vietnam war; the Gulf war; the Afghan and Iraqi wars; the assassinations of President Kennedy, Robert Kennedy, and Martin Luther King, Jr.; Watergate; the Clinton impeachment trials; the AIDS epidemic; the terrorist attacks of September 11, 2001; Hurricane Katrina; and the election of the first African American president. They have experienced the political leadership of 15 presidents. During their lives, they have adapted to dramatic technological innovations in communication, transportation, manufacturing, economics, food production, leisure activities, and health care. They have also experienced striking changes in cultural and political values.

One consequence of a long life is the realization that change is a basic element of all life at the individual and societal levels. Sometimes, these changes appear cyclical; at other times, they appear to bring real transformations. For example, people who are now age 80 lived during World War II when women were involved in the labor market while men served in the military; the 1950s, when many women withdrew from the labor market and committed themselves to working at home; and the 1970s up to the present when it has become normative for women to be employed outside the home, even when they have very young children. The patterns of behavior that younger adults might view as normative and necessary, elders may recognize as part of fluctuating social or historical conditions.

Within the framework of an extended life, elders have opportunities to gain a special perspective on conditions of continuity and change within their culture. As society becomes more accustomed to having a significant group of elders functioning in the community, some scholars anticipate that a *culture of aging* will emerge in technological societies. This culture is likely to provide more opportunities for the expression of the pragmatic wisdom accumulated over a long lifetime through theater, music, the arts, and critical commentary. At the same time, new roles will evolve for successful agers as mentors and advisors to the young (Kunzmann & Baltes, 2005). Some professional societies, like the American Sociological Society, have created a network for retirees to share their views and exchange ideas. In the United Kingdom, pensioners have created the Retirement Lounge, an online setting where retirees can interact and share their experiences:

> Social interaction is extremely important when we leave work for good. We are no longer in the working environment to share a joke or gossip with our colleagues. Sadly, many retirees get trapped in their home environment with no one to talk to apart from their family members, if they are fortunate to have them around. With that in mind, this portal is set up to serve the needs of senior citizens. This is a Pensioners Corner. With our pool of experience and knowledge base we should be able to help each other. (retirement-lounge.com, 2013)

Another online resource is sponsored by TIAA, myretirement.org. It has thousands of members who share ideas about weekly topics, access information about current trends, respond to surveys about topics of relevance to older adults and read about the results, share aspirations, thoughts, and photos with others. Other sites where older adults are sharing their expertise include coolgrandma.com, senior.com, seniornet.org, and senioryears.com.

An international group of leaders, *The Elders*, is a different example of how people can bring their life experiences to bear to address critical issues (www.theelders.org). *The Elders,* founded by Nelson Mandela, was formed to help address some of the serious and seemingly intractable problems that plague our world. A premise of this group is that in traditional societies, the oldest members of the group were looked to for their wisdom and guidance in efforts to resolve difficult conflicts. In today's world, where the conflicts are often of an international and intercultural nature, the global community is in need of a group of respected and trusted leaders who can offer guidance without a vested interest in a particular national, industrial, or religious advantage. The founding members of *The Elders* are characterized as "trusted, respected worldly-wise individuals with a proven commitment and record of contributing to solving global problems." *The Elders* hope to share their wisdom, forged over their long lifetimes and opportunities for international leadership.

As the example of *The Elders* suggests, a psychohistorical perspective contributes to the wisdom that the very old bring to their understanding of the meaning of life. As a result of living a long time, a person becomes aware of life's lessons as well as its uncertainties. The integration of a long-term past, present, and future combined with an appreciation for the relativistic nature of human experience allows these adults to bring an acceptance of alternative solutions and a commitment to essential positive values.

We are all part of the process of psychosocial evolution. Each generation adds to the existing knowledge base and reinterprets the norms of society for succeeding generations. Elders are likely to be parents, grandparents, and great-grandparents. Many are seeing their lines of descent continue into the fourth generation, which will dominate the 21st century. The opportunity to see generations of offspring brings a new degree of continuity to life, linking memories of one's own grandparents to observations of one's great-grandchildren. We can expect the value of the oral tradition of history and storytelling to take on new meaning as the elders help their great-grandchildren feel connected to the distant past. We can also expect a greater investment in the future, as elders see in their great-grandchildren the concrete extension of their ancestry three generations into the future.

Erikson (Erikson et al., 1986) identified the emergence of these tendencies in the very old in the following excerpt:

> The elder has a reservoir of strength in the wellsprings of history and storytelling. As collectors of time and preservers of memory, those healthy elders who have survived into a reasonably fit old age have time on their side—time that is to be dispensed wisely and creatively, usually in the form of stories, to those younger ones who will one day follow in their footsteps. Telling these stories, and telling them well, marks a certain capacity for one generation to entrust itself to the next, by passing on a certain shared and collective identity to the survivors of the next generation: the future. (p. 331)

FURTHER REFLECTION: *Explain the concept of a psychohistorical perspective and evaluate how it contributes to psychosocial development in elderhood. Reflect on any conversations you have had with someone who offered a unique perspective on time, history, and self-awareness.*

Traveling Uncharted Territory: Life Structures in Elderhood

OBJECTIVE 4 Summarize elements of the lifestyle structure in elderhood, especially living arrangements and gender roles, and analyze the impact of these life structures for continued well-being.

How should elders behave? What norms exist to guide their social relationships or the structure of their daily lives? When we talk about traveling uncharted territory, we are assuming that elderhood is a time of life for which there are few age-specific social norms. Elders are creating their own definitions of this life stage.

Changes in role relationships—especially role loss in later adulthood—present significant challenges to the preservation of a coherent self-concept. In early adulthood, there is an opportunity to engage in many new roles and to establish a lifestyle that expresses the priorities of one's personal identity. In middle adulthood, the pressure of life roles and their competing demands may be at their peak. During later adulthood, the challenge is to establish an integrated sense of self that helps to compensate for the loss of salient life roles and to protect the person from a sense of despair.

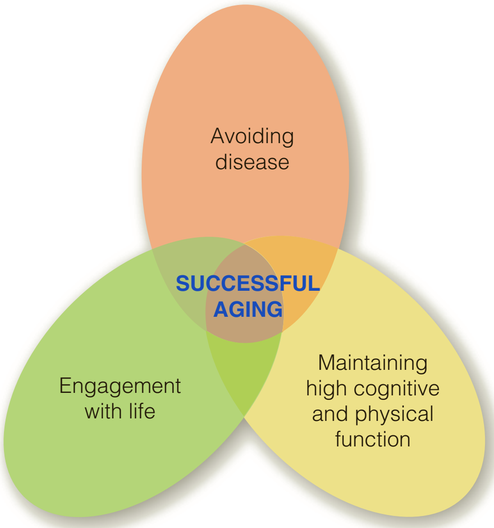

FIGURE 14.2 ▶ COMPONENTS OF SUCCESSFUL AGING

Source: Adapted from Successful Aging, by J. W. Rowe & R. L. Kahn, 1998, New York: Pantheon.

In elderhood, those who cope most effectively create a new, modified lifestyle. They are able to focus on certain valued characteristics of the self and to optimize them despite changes in their social and physical resources (Diehl, Hastings, & Stanton, 2001). One of the key features of this emerging lifestyle is a sense of purpose in life. Those who have a strong sense of meaning, who view their lives as meaningful to the self and significant for the lives of others, live longer, healthier lives than those without this sense of meaning (Krause, 2009; Macdonald, Wong, & Gingras, 2011).

Successful aging is a biopsychosocial process. The MacArthur Foundation Research Network on Successful Aging (Rowe & Kahn, 1998) introduced an interdisciplinary perspective on the distinction between usual and successful aging. Those characterized by **usual aging** may be functioning well but are at high risk for disease, disability, and reduced capacity for functional independence. In contrast, the **successful agers** are characterized by three interdependent features (see FIGURE 14.2 ▶). They have a "low risk of disease and disease-related disabilities; high mental and physical function; and active engagement with life" (p. 38). This last feature, **active engagement,** is a frequently repeated theme in the field of gerontology.

In an effort to describe the norms that older adults use to guide their conduct, researchers asked older adults from New York City and Savannah, Georgia, to respond to six pictures similar to the two drawings in FIGURE 14.3 ▶ (Offenbacher & Poster, 1985). The responses to the following two questions were used to construct a code of conduct: "How do you think that people who know this person, such as family or friends, feel about him or her?" and "How do you feel about this person?" Four normative principles were found in the responses:

1. Don't be sorry for yourself.
2. Try to be independent.
3. Don't just sit there; do something.
4. Above all, be sociable.

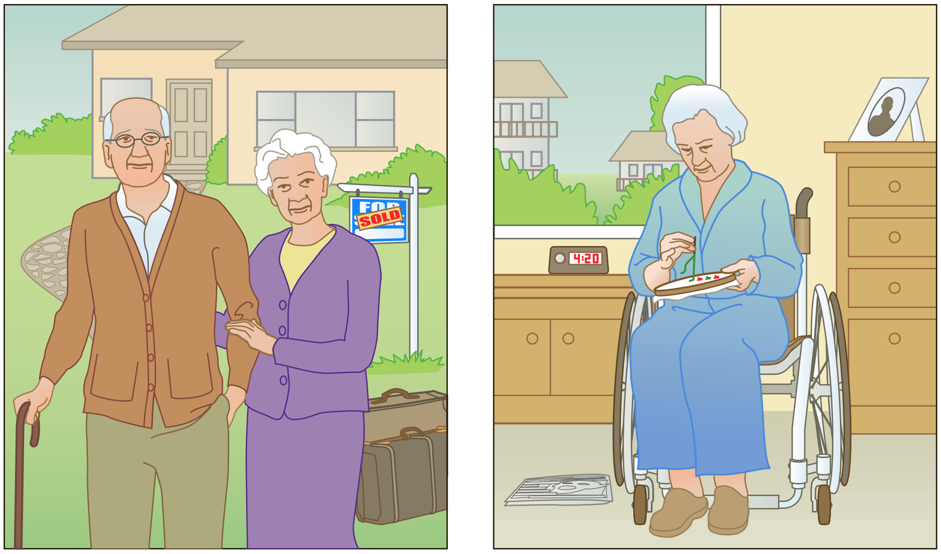

FIGURE 14.3 ▶ TYPICAL DRAWINGS THAT RESEARCHERS MIGHT USE TO ESTABLISH THE SOCIAL NORMS OF VERY OLD PEOPLE

Source: Drawings based on Offenbacher and Poster, 1985.

This code of conduct suggests that older people believe that being sociable, active, and independent constitute successful living in later life. Of course, older adults are not alone in valuing these qualities. However, these norms are important as sources of self-esteem for this age group. They promote a sense of vigor and a shield against depression or discouragement.

The themes "Don't be sorry for yourself" and "Don't just sit there" suggest that elders continue to see their lives as precious resources that are not to be wasted in self-pity and passivity. The emphasis on activity as opposed to meditation reflects the Western cultural value of a *sense of agency*—thinking is not as highly valued as action. In contrast, doing things, having an impact, and receiving the feedback that action stimulates provide the keys to successful living. Subsequent studies have supported the idea that finding meaning in one's existence, continuing to experience a sense of social competence, and perceptions of self-efficacy help older adults maintain a sense of well-being (Onedera & Stickle, 2008). In today's technologically rich environment, there are many opportunities for engaging in intellectually stimulating and socially engaging activities, even if one's physical mobility is limited. By continuing to participate in intellectually complex and challenging leisure activities—such as reading stimulating books and magazines; participating in online discussion groups; going to museums, concerts, and plays; traveling; or participating in hobbies that require decision making and problem solving—older adults contribute to preserving their intellectual flexibility (McDonough, Haber, Bischof, & Park, 2015; Schooler & Mulatu, 2001).

The desire to preserve a sense of control and agency is expressed across ethnic groups despite differences in health problems, loss of loved ones, and poverty. However, the ways that women define empowerment and experience successful aging is related, in part, to their cultural values and worldview. In a study of women between the ages of 60 and 80, nine different ethnic groups were self-defined by the participants: English, British Muslim, African Caribbean, Dominican, British Irish, Pakistani, British Polish, Indian, and Bangladeshi (Wray, 2003). For some of these women, freedom from the burdens of care for their aging family members or children was a valued opportunity for empowerment in later life. A number of women engaged in forms of group religious services and the related opportunities for social interaction, volunteer work, and prayer, which created feelings of social inclusion and agency.

> I am baptized Sikh and value religion to guide me and have focus in life. My religion has influenced my life very positively; this has helped me to care for my husband and cope with stressful events. I have planned days when I visit friends and attend religious activities. These are also my means of socializing. We offer each other support and get involved in charity work. (Wray, 2003, p. 519)

For some women, paid employment or volunteer work keeps them connected to society and provides feelings of being in control of their daily lives. Some women spoke of their time with their grandchildren and the responsibilities they had for their grandchildren's care as contributing to a sense of purpose and well-being. In some cultural groups, the opportunity to strengthen their connection with their religious and ethnic communities created a form of collective agency. In other cultural groups, the opportunity to continue to express self-reliance and control over daily life was especially significant. Among most of the women, some form of interdependence and participation in meaningful social relationships played a key role in sustaining feelings of agency and continued self-worth.

The fact that elders must carve out new patterns of adapting to later life is illustrated in three specific areas of functioning: living arrangements, gender-role definitions, and romance and sexuality.

Living Arrangements

Approximately 78 percent of U.S. adults ages 75 and older own their own homes. However, the pattern of **living arrangements** changes after age 75, especially for women. Before that age, the majority of older adults live in family households, mostly as married couples. Among adults ages 75 to 84, however, only 53 percent live with a spouse; the others either live alone or with family or nonrelatives. The pattern differs by gender. Among women ages 75 to 84, 37 percent are married and live with their spouse; among men ages 75 to 84, 71 percent are married and live with their spouse (U.S. Census Bureau, 2013d). Older women are less likely than men to remarry after the death of their spouse, and older women are less likely to live with other family members than they were in the past. For unmarried elders, functional status and cognitive functioning are key factors that lead to living with one's children or other relatives (Liang et al., 2005).

Living arrangements among older adults are linked to cultural values associated with individualism and independence or collectivism and interdependence. In a comparison of living arrangements in 43 countries, older adults were the most likely age group to live alone. However, in Africa it was more common for older adults to head up a large household that included young children than in other countries. In Asia, co-residence with adult children was more common than in Africa. When older adults lived with their children, co-residence with adult sons and their families was more common in Asia and Africa, but co-residence with adult daughters and their families was more common in Latin America. In countries with higher levels of education for the general population, families were more likely to have nuclear households with older adults living alone (Bongaarts & Zimmer, 2002).

Living Alone. Increasing numbers of women are establishing a new single lifestyle in which they function as heads of households at ages 75 and older. In 2014, 46 percent of women aged 75 and older lived alone. Anglo American and African American women are more likely than Asian American women and Latinas to live alone (Administration on Aging, 2014). Older unmarried Asian American women, for example, are much more likely to live with other family members than to live alone in comparison to Anglo American women of similar economic and educational backgrounds. Though still in need of social interaction and support services, they are often relieved of the responsibilities of caring for spouses who were ill. Depending on their own health, these women may be freer to direct their time and interests toward their friends, grandchildren, hobbies, and activities than they have been at any other time in their lives. In a qualitative study of older widows' experiences, four themes emerged: (1) making aloneness acceptable, (2) going my own way, (3) reducing my risks, and (4) sustaining myself (Porter, 1994). One aspect of this process of adaptation, often linked to "going my own way" and "reducing my risks," is a decision to move from one's residence. In a longitudinal study of residential mobility, individuals were interviewed over a 20-year period. Widowhood was found to be a significant event that triggered a decision to move, often within the first year after becoming widowed (Chevan, 1995).

iStockphoto.com/isitsharp

Most older women who live alone adapt well to this independent life style. Charlotte enjoys her needlepoint, has frequent visits from family and friends, and does not have to take care of anyone but herself.

The pattern of elderly women living alone is similar in Canada, the United Kingdom, and many other northern European countries, but it is not as common in southern Europe and developing countries where both older men and women, whether married or widowed, live in multigenerational families. For example, data gathered in four Asian countries—Thailand, Singapore, Philippines, and Vietnam—in the mid-1990s found that from 60 percent to 90 percent of older adults lived with their children and grandchildren.

The case of Japan illustrates the possible impact of modernization on the living arrangements of the elderly. In 1960, about 90 percent of older adults lived with their children (or one might say that the children lived with them in their households). By 1990, this type of living arrangement had declined to 50 percent. Both the increasing longevity and improved financial resources of older adults contribute to this trend toward independent housing, which is coupled with a continued desire for close kinship ties (Kinsella & Velkoff, 2001).

In contrast to those older women who live alone and those who live with a male partner, an emerging strategy is for several older women to live together. This alternative addresses the increasing costs of housing in many communities as well as the problem of the health and mental health risks of social isolation and loneliness in later life. Women of the baby boom generation are more likely to have experienced divorce and have smaller families than the previous generation of older adults. Many of these women have developed and nurtured friendships with other women from their high school and college years, in the workplace, and through community participation. As they begin planning for later adulthood, the idea of sharing the costs and responsibilities with good friends can be quite appealing. "We lived together in dorms and sororities. We shared apartments after graduation. We traveled together. We helped each other through divorce and the death of our parents. Why not take it to the next level?" (Gross, 2004, p. 1). A number of online services and agencies, like Golden Girls Housing in Minneapolis, are emerging to help women find others who want to live in shared housing (Abrahams, 2013).

Interstate Migration. The great majority of older adults (more than 95 percent) remain in their home communities as they age, many preferring to stay in their own home even after their children move out and their spouse dies. Yet the trend toward interstate migration has increased since the mid-1960s. In 2012–2013, 48,000 people aged 75 and older moved from one region of the country to another (U.S. Census Bureau, 2013d). Many of these older interstate migrants will live out their lives in communities in which they did not grow up, work, or raise their children. They are pioneers, establishing new friendships, community involvements, and lifestyles. Another group of older adults return to their birth state, especially after one's spouse dies or, in the case of serious disability, in order to be close to family caregivers (Stoller & Longino, 2001). In the face of new physical limitations, older adults may want to remain independent but require more help. By moving back to their home community, they are more confident about being able to draw on needed support from family and friends (Rowles & Ravdal, 2002). In addition to these permanent moves, many older adults participate in seasonal migration—residents from southern states go north for the summer, and residents of northern states go south for the winter. Over time, some of these seasonal migrants decide to establish a permanent residence in the state they visit. This is especially likely for northern residents who establish permanent residence in the South (Smith & House, 2006).

Housing Options. Differences in lifestyle, health, interest, ability to perform daily activities, marital status, and income enter into the very old person's preference for housing arrangements. Housing for the elderly has expanded dramatically, and developers have experimented with a great variety of housing configurations that are intended to meet the special needs of particular aging populations (Shapiro, 2001). These options range from inner-city hotels for those with minimal incomes to sprawling luxury villages with apartments, medical clinics, and sponsored activities. Retirement communities are typically age-restricted residences. They may be apartments in a high-rise, townhouses, or homes with shared recreational resources. Often, they provide the option for prepared meals or a communal dining center.

The baby boomers are "pushing the envelope" in many social institutions, not the least of which is housing. Their ideals about aging influence the kinds of living arrangements they seek: "Stay active, keep learning, develop and preserve relationships; and have fun for as long as possible" (Abrahms, 2011). The following housing alternatives suggest innovative approaches to benefit today's elders (Abrahms, 2011).

Niche Communities. For people with similar backgrounds and interests. These communities are for people who are still active and relatively healthy, but who may want some assisted care resources. The most common of these are the 50 or more university-based communities where alumnae, retired faculty, and others can enjoy classes, lectures, cultural and sporting events, as well as the health care resources of the university.

Intergenerational Co-housing. For families with children as well as elders. The group of residents buy a property, design the housing units and common features, and share the responsibilities of the management of the property. Residents live in separate homes but share communal space for large group meals, recreational facilities, some guest quarters, and resources like, arts, media, exercise, or meditation rooms depending on the interests of the residents.

The Village Model. For people who want to remain in their own homes, the village model provides a collaborative approach to resources. People join the village with a membership fee for the individual or household. With this fee, they have access to services including transportation, health professionals, home maintenance services, and other resources. The village may offer group prices for tickets, sponsor outings and group activities, and hold suppers for members.

Life satisfaction in a retirement community may depend on the fit between one's marital status and the demographics of the community. One study assessed the life satisfaction of widows who were living alone in retirement communities. When widows outnumbered married couples in the community, the widows had a high frequency of seeing friends and participating in activities. However, when married couples outnumbered widows, the widows experienced less satisfaction and were more socially isolated (Hong & Duff, 1994).

The majority of elders live in urban areas. As a result, any economic factors that affect the **housing options** in urban communities have a significant impact on the living arrangements of older adults (see the **Applying Theory and Research** box The Impact of Gentrification on the Elderly). Roughly 23 percent of women and 14 percent of men over the age of 80 live below the supplemental poverty threshold (Cubansi, Casillas, & Damico, 2015). Many have a fixed income and depend on the quality of community resources and social support for their well-being; moving can be an especially difficult life event, adversely affecting overall well-being (Pynoos, Caraviello, & Cicero, 2010).

Institutional Care. About 1.3 million adults older than 65 live in **skill care facilities** (sometimes referred to as nursing homes). This includes any arrangement with three or more beds that provides nursing and personal care services (U.S. Census Bureau, 2012). **Nursing homes** provide nursing care and rehabilitation for people who have severe functional limitations as a result of acute illness, surgery, or advanced dementia. The likelihood of institutionalization increases with age and limitations in family support. In 2011, about 1 percent of those ages 65 to 74 were living in a nursing home, but 11 percent of those 85 and older were in this kind of facility. About 75 percent of people in nursing homes do not have spouses. The likelihood of a person living in a nursing home increases when there is no family member who can help to manage daily living needs (Harris-Kojetin et al., 2016).

The Green House is a new style of nursing home on a smaller scale. Typically 10 residents live in private bedrooms and bathrooms but share a living and dining room area that looks like a single-family home. These rooms open onto a porch or backyard. The group of 10 is supported by a nursing staff that provides daily medical care as well as meals. The residents take care of themselves to the extent of their ability, and the staff gets to know the residents quite well (Gustke, 2015).

People tend to think that once older adults are admitted to a nursing home, they stay there until they die. In fact, there is a high annual turnover among nursing home residents. The average length of stay is 6 months. The U.S Department of Health and Human Services estimates that about 37 percent of people will use some type of nursing or assisted living care facility in their lifetime, and that people use this type of care for an average of 12 months in their lifetime (longtermcare.gov, 2013). Often, a person enters a nursing home for a period of convalescence after hospitalization and then returns home or to a setting that provides less intensive care.

Many nursing homes are part of a **continuing care retirement community**—a residential setting offering housing and medical, preventive health, and social services to residents who are well at the time they enter the community. In 2014 there were over 800,000 residents living in residential care communities. Once admitted, they are guaranteed nursing care if they become ill or disabled (Harris-Kojetin et al., 2016).

APPLYING THEORY AND RESEARCH TO LIFE

The Impact of Gentrification on the Elderly

Gentrification is a process of urban renewal or renovation in which new home owners and developers invest in the rehabilitation of neighborhoods that have been deteriorating due to lack of maintenance and upkeep of the properties. Middle and upper income residents move into areas that have been deteriorating, often displacing poorer residents who have lived in that area for some time. To make investment in new construction and rehabilitation of older housing stock profitable, developers must be able to attract residents who can pay higher rents such as professionals and managers (the urban gentry). Once this process gets under way, landlords have an incentive to evict low-income residents who may have lived in the neighborhood for a long time in favor of more affluent tenants who can afford higher rent (Renn, 2013).

Several consequences of gentrification can have a negative impact on the housing options of older adults. First, rental apartments are converted to condominiums that older adults cannot afford. Second, in areas where there is no rent control, the rent rises above the rate that the older person is able to pay. In a report on the gentrifying process in New York City, rents in gentrifying neighborhoods increased 34 percent from 1990 to 2014. In citywide plans for 51,000 new rental units, only 3,000 were identified as low-income housing (NYU Furman Center, 2016). Some developers promise to build low-income housing and may receive state and federal funds to support these units, but the low-income housing and related community improvements never materialize (Patel, 2013).

Where there is rent regulation, some landlords use harassment to force out the original residents. Third, properties that have been used as single-room-occupancy hotels are demolished and new structures are built. Single-room-occupancy hotels provide low-cost housing and social support to many older adults who live alone. From 1970 to 1982, more than half the single-room-occupancy units in the United States were lost to various urban gentrification projects (Hopper & Hamberg, 1986). A similar study of gentrification in London found a significant displacement of the elderly, with the hidden costs of overcrowding in family, friends', or relatives' homes; homelessness; and expanded unmet housing needs (Atkinson, 2000).

In addition to reducing access to affordable housing, the disruption in older adults' living arrangements can have health implications due to dispersion of the person's social support network, reduced access to public transportation, and less readily accessible sources of basic goods and services (Centers for Disease Control and Prevention, 2012a).

Although gentrification poses threats to housing for the elderly, the alternative of ongoing neglect and decay in urban neighborhoods brings its own risks—especially increased crime, health and safety hazards, and lack of services. Over time, people with more resources leave these neighborhoods, making them vulnerable to continued deterioration.

Writing about the process of gentrification in Los Angeles, David Zahniser described it as follows:

> That, in a nutshell, is the most maddening thing about gentrification—its very duality, the way in which it simultaneously delivers pleasure and pain, miraculous benefits and terrible consequences. As middle-income residents move in, neighborhoods that once heard low-flying helicopters and automatic-weapons fire have found a greater measure of peace. Working-class families who scraped together the money to buy homes in the mid-1990s have happily cashed out, making hundreds of thousands of dollars en route to a five-bedroom home in Fontana, Las Vegas or Phoenix. Those who stay behind, however, frequently find themselves in a neighborhood they don't recognize. And those who rent in a rapidly gentrifying neighborhood discover that they gained physical security while losing economic security, with rents rising steadily and the inventory of reasonably priced homes shrinking. (Zahniser, 2006, p. 2)

More positive approaches suggest a gradual rehabilitation or redevelopment of urban communities that preserves the identity of the neighborhood but encourages new building and new businesses at a slower rate of growth (Centers for Disease Control and Prevention, 2012a). One idea is to offer developers incentives to include rental or sale units for low- and moderate-income residents as part of their design. Some cities have placed a freeze on the conversions of rental units to condominiums. Others have created community land trusts where residents own the units or homes they live in, but the community owns the land, thus helping to control its use. This strategy is intended to help protect the neighborhood atmosphere and tone that have been created by its long-term residents.

Critical Thinking Questions

1. Explain why older adults are especially likely to be impacted by gentrification. Why might the increased housing costs be especially difficult for them?
2. Describe the particular stressors that an older adult might face if gentrification results in a loss of their long-term residence.
3. Speculate about impact on psychosocial development of moving to a new neighborhood for people who are in their 80s or 90s.
4. Hypothesize about why the elderly might want to remain in their apartment or home, even if the neighborhood is deteriorating.
5. State your opinion about the obligations that local governments and developers should assume for the housing needs of the elderly when older housing stock is renovated or replaced.

Lisa S./Shutterstock.com

At age 82, Randall is receiving physical therapy and rehabilitation in a nursing care facility. He expects to return to independent living in a few weeks.

The advantages of a continuing care community are described by Glenn Smith:

> "We'd seen a lot of people our age struggle when one went into a skilled nursing facility 6 miles away," says 76-year-old Glenn Smith. "Then someone has to drive Momma over to see Daddy every day." So Smith and his wife, Kathleen, moved to a CCRC (continuing care retirement community) atop a hill overlooking Oregon's Rogue River Valley. A nursing home is just a short walk from their spacious three bedroom cottage. Smith, who is a retired college administrator, has one bit of advice: Move in while you are younger and healthy in order to take full advantage of the activities—and pay a lower entry fee. (Shapiro, 2001, p. 60)

Aging in Place. The fastest growing component of the Medicare program is **community-based long-term health care**, which provides medical and social services to those who are chronically ill and eligible for institutionalization but who live in the community. In 2013 close to 5 million clients received services from home health agencies; 57 percent were age 75 and older (Harris-Kojetin et al., 2016). At their best, these programs are designed to complement and support informal caregiving, supplementing and providing relief for family members and friends who are trying to care for the very old. They bring comfort to the very old clients who prefer to remain in their homes.

These programs also offer flexibility by providing needed services and modifying them as a person's condition changes. A home health service may provide a case manager who can identify the required services and coordinate a program of home care providers, services, and adult day care to meet the needs of the client and the client's support system. Funding is person-centered rather than institution-centered, which allows services to be altered in order to support movement from institution to home-based care. Long-term home health care programs evolve in response to the pattern of need that emerges in a community and the quality of the services available. As the programs develop, their emphasis tends to shift from providing services to those who would otherwise be institutionalized to preventing institutionalization among a high-risk population (Kasper, 1997; Kaye, 1995; Medicaid.gov, 2013; U.S. Department of Health and Human Services, 2005).

The benefits of remaining in one's home, despite serious limitations in functional independence, are (1) preserving one's sense of autonomy and dignity, (2) reducing expenses, and (3) sustaining relationships with family and friends. By remaining in one's home, a person has greater control over the way the environment is adapted to one's changing abilities and needs. The personal and private meaning of the home environment supports one's identity and helps preserve a sense of "keeping up with dignity and pride" (Rowles & Bernard, 2013; Witse, Vik & Ytterhus, 2012). In contrast, the move to a nursing home tends to be associated with higher levels of dependence and greater emphasis on "going along with the program" rather than initiating one's own plans and projects.

In a comparison of older women living in their homes and those living in a nursing care facility, researchers were interested in how the living arrangements might influence cognitive problem solving. The home-based group became more engaged in the hypothetical problems, their solutions suggested a greater sense of perceived control over the solutions, and they approached the problems in a more abstract, relativistic manner (Collins, Luszcz, Lawson, & Keeves, 1997). These results suggest that nursing home environments may undermine cognitive functioning by reducing the need for independent problem-solving activity. However, as the case study about Mr. Z suggests, there are nursing home residents who retain their positive spirit and are able to help others while receiving the support they require given serious physical disabilities.

— Case Study Mr. Z —

The following case illustrates the importance of psychological attitudes in allowing a person with serious physical problems to play a meaningful role in a social setting for the frail elderly. Mr. Z's outlook helps him maintain his vitality and express his love of life.

Mr. M. L. Z is an 89-year-old White male of Eastern European origin. He lives in a midsized nursing home in the Midwest. Many of his daily activities revolve around circulating among the facility's residents, chatting, playing cards, reading to them, and "fetching things." Most important, Mr. Z carries his old battered violin with him and at the drop of a hat will play a tune or break into song in a surprisingly strong, clear, melodic voice. He claims to be able to sing songs in any one of seven languages, and with the least encouragement will try out several for anyone who will listen.

Mr. Z is small (5′ 3″), frail looking, and completely bald. He has facial scars and wears extremely thick-lensed glasses. He seems to be known and well liked by practically all residents and staff of the facility in which he resides, and by many visitors there as well.

He recalls a colorful history. He "escaped" his homeland at the tender age of 16 to avoid compulsory military service and fled to Russia. There he was inducted into the army, and was subsequently sent off to duty in Siberia, where he lived for about 6 years. After another tour of duty in a border patrol he deserted, he made his way across Europe, and eventually came to the United States. Here he took odd jobs, educated himself, and in time "got into show business"; he became a vaudeville prompter. In time his contacts in entertainment took him around the world. Yet time took its toll.

He tells of marrying a woman with whom he lived for almost 40 years. They had no children and she died some 15 years ago. Following her death, he began to experience a series of physical difficulties. An operation for cataracts left him with the need for very thick glasses. At one time he had a toupee made, which he has not worn for some time. One leg was amputated because of a diabetic condition, and he now wears a prosthetic leg. In addition, he wears a hearing aid, false teeth, and, for the last year, a heart pacer. Several years ago he experienced what he calls a small stroke, which left him "mixed up" for a few days. But he "worked this out," he reports, by "walking a lot," an activity in which he engages frequently.

Mr. Z says he has never smoked and drinks only on occasions or holidays, and then only to a limited degree. He scorns food fads, and eats mostly fresh fruits and lots of vegetables; he loves fish and drinks lots of tea.

Despite all his troubles, Mr. Z maintains what is apparently a cheerful, optimistic view of life and circumstances, while he pursues his hobby of energetically helping his fellow residents keep their spirits up and their interests high. He is very highly regarded and seen as filling a very important role in his nursing home as a storyteller and entertainer.

CASE ANALYSIS Using What You Know

1. Imagine that you were having lunch with Mr. Z. What questions would you want to ask him?
2. Summarize the physical challenges of aging with which Mr. Z must cope.
3. Explain why Mr. Z might be living in a nursing home. What supports does he need?
4. Describe Mr. Z's psychohistorical perspective. What insights does he have about history, time, and self-awareness?

Gender-Role Definitions

The way in which elders view masculinity and femininity is yet another aspect of traveling uncharted territory. The idea of **gender-role convergence** suggests a transformation of gender-role orientation during midlife. According to this theoretical perspective, men become more nurturant and more concerned with social relationships. Women become more assertive and concerned with independence and achievement. As a result, men and women become more androgynous and, in that sense, more similar in gender orientation during later life (Gutmann, 1987).

Evaluating the Concept of Gender-Role Convergence. The extent to which men and women become more similar in outlook and behavior in later adulthood and elderhood is a subject of controversy. Few data from longitudinal or cohort sequential studies are available to address this topic. Cross-sectional data collected from earlier cohorts of men and women across a wide age span from early adulthood to elderhood have focused on men's and women's endorsement of affiliative and instrumental values. Men and women appear to be similar in their **affiliative values**—that is, the values placed on helping, pleasing, or enjoying the companionship of others. At each age, men are more invested than women in **instrumental values**—that is, the values placed on having an impact, engaging in challenging activities, and making things happen. However, the youngest age groups value instrumentality more highly and devote more time to it than the oldest age group. Thus, gender differences in instrumentality persist, but instrumentality becomes somewhat less important for older men and women. Affiliative behavior is equally important for men and women at both ages (Fultz & Herzog, 1991).

The stereotypes that are applied to aging men and women reflect similar patterns. College students and older adults (with a mean age of 70) were asked to generate characteristics in response to one of four target stimuli: a 35-year-old man, a 35-year-old woman, a 65-year-old man, and a 65-year-old woman (Kite, Deaux, & Miele, 1991). Age stereotypes were more prevalent than gender stereotypes. The attributes that were used to characterize older men and women were similar and distinct from the attributes used to characterize younger men and women.

The older target people were evaluated more negatively by the younger participants, but not as negatively by the older participants. These negative judgments included unattractive physical qualities as well as irritable and depressed personality qualities. Moreover, younger participants were more likely to characterize both male and female older target people as lacking in instrumental traits, such as achievement orientation and self-confidence. However, they did not view older target people as lacking in affiliative traits, such as caring about others or being kind or generous. Thus, the gender-role convergence that has been hypothesized as taking place with advanced age is reflected in the stereotypes that younger people apply to older adults.

Gender-role convergence, where it is observed, may be due to changing circumstances rather than to a normative pattern of development in later life. For example, many older women experience a transition from living with their husbands to living alone after age 75. This change is linked to new demands for independence, self-reliance, and agency. Women who are able to meet these challenges by developing independent living skills, making effective use of social supports and community resources, and initiating new relationships are likely to experience a heightened sense of well-being.

For many older married couples, the physical effects of aging bring new needs for assistance in some of the tasks of daily living. Because men usually marry younger women, they are more likely to require the assistance of their wives in the later years of marriage, thus shifting the balance of power by increasing the sense of **dependency** among older men and the sense of instrumentality among older women. This may be especially true when husbands retire while their wives continue to work, when husbands can no longer drive and depend on their wives for transportation, or when, due to health constraints, husbands are restricted from performing the household tasks that once were their domain, such as mowing the grass, shoveling snow, repairing the home, or other tasks requiring muscle strength and endurance.

iStockphoto.com

After 60 years of marriage, Ann and Ted still get quite a kick out of being together. Their lives are sprinkled with many moments like this, when a glance or an expression brings out a loving smile.

In contrast, among adults 75 years and older more women than men have difficulties with mobility and require assistance in the tasks of independent living. For these couples, men may assume new caregiving roles, combining nurturance with feelings of agency. Thus, health and fitness more than gender may guide the nature of dyadic interactions among older couples. As men and women become more equal with respect to power and resources in their marital relationship, there may be fewer clear-cut gender expectations. Still, to the extent that gender-role distinctions help stabilize a relationship, older adults may be reluctant to make dramatic changes to the way their relationships have been structured (Silver, 2003). We do not know whether new cohorts of the elderly, especially the baby boomers, who are accustomed to balancing work and family life, will arrive at later life with different views about instrumentality and its association with gender (Muhlbauer, Chrisler, & Denmark, 2015; Robbins, Wester, & McKean, 2016).

Romance and Sexuality

Romance, intimacy, and sexuality remain important among older couples. The majority of couples who have enjoyed a close, sexually active relationship report little change in satisfaction from age 60 to 85. Some couples explore different ways of experiencing sexual pleasure in later life, and others report a more relaxed, sexually satisfying quality in their lovemaking. Thinking back to Sternberg's (1988) model of the three dimensions of love, long-lasting marriages tend to be more companionate in nature, emphasizing intimacy and commitment over passion.

Research on sexuality in later life confirms that many older adults have sexual needs, benefit from sexual expression, and are able to be sexually active. A national survey of adults ages 60 and older found that more than half were sexually active, meaning that they had intercourse, oral sex, anal intercourse, or masturbated at least once a month (Dunn & Cutler, 2000). Sexual activity declined with age, but 20 percent to 25 percent of those in their 80s were still sexually active. Older couples may find greater satisfaction in intimate physical contact, such as kissing and caressing, and experimentation with new ways of experiencing sexual stimulation as genital intercourse becomes less frequent. Following along with the idea of gender-role convergence, men and women become more similar in their sexual behavior and more harmonious in their lovemaking (Crooks & Bauer, 2013).

One of the greatest challenges to continued romantic and sexual intimacy in later life is widowhood. Despite the fact that older men are much more likely to remarry than older women, remarriage is relatively uncommon in later adulthood and elderhood. In a study of older couples that followed men and women 6 and 18 months after widowhood participants were asked two questions about their romantic interests: "At this point do you have any interest in dating?" which was answered *yes* or *no*, and "Someday I would like to remarry," answered on a scale from *not true at all* to *very true*. They were also asked if they were dating. At 6 months after widowhood, men were more likely to want to be dating than women (17 percent versus 6 percent), more likely to want to remarry (30 percent versus 16 percent), and more likely to be dating (15 percent versus less than 1 percent). At 18 months after widowhood, men were still more likely to want to be dating (37 percent versus 15 percent) and more likely to be dating (23 percent versus 9 percent), but about equally likely to want to remarry (26 percent versus 19 percent). The most important predictor of whether men or women wanted to date or remarry was the quality of their social support system. In general, women had more supportive relationships with friends than did men prior to widowhood. The more social support men had, the less likely they were to express interest in remarriage. Men and women who had comparable levels of social support from friends were equally disinterested in remarriage (Carr, 2004).

This research suggests that the picture we have about gender differences in motivations to find a new partner after widowhood may need to be revised. First, although more men than women are interested in new romantic relationships, the majority of men do not express this interest. Second, when social support systems are comparable, men and women are about equally likely to reject the idea of a new romantic relationship.

One criticism of this research was the way in which interest in a new partner was defined, limiting the alternatives for romantic relationships to dating and marriage. Potential financial consequences may make remarriage undesirable. For instance, a widow may lose her husband's pension or Social Security benefits if she remarries. Given the potential costs of remarriage in later life, older adults may be looking for a different kind of intimacy that does not require the responsibilities of co-residence or the legal and financial considerations of marriage (Davidson, 2002; Ghazanfareeon, Karlsson, & Borrell, 2002; Moorman, Booth, & Fingerman, 2006). Some older couples cope with this problem by living together instead of marrying. From 2000 to 2010, in the United States the number of unmarried, heterosexual couples over the age of 65 who were living together increased from 193,000 to 575,000 (Creamer, 2011).

Ageism and Sexuality. Older adults continue to face negative attitudes about sexual activity that may inhibit their sexual behavior. These attitudes include assumptions that very old adults do not have sexual desires, they cannot have intercourse because of sexual dysfunction, sex may be dangerous to their health, they are physically and sexually unattractive, and it is morally wrong or perverted for older adults to be sexually active (Crooks & Bauer, 2013). Current cohorts of elders may have limited knowledge about sexuality and aging. Increasing knowledge through various sex education programs can increase permissive attitudes about sexuality among older adults (Hillman & Stricker, 1994). These interventions have involved elderly people, nursing students, college students, nursing home staff, and adult children of aging parents. However, increased knowledge does not always result in more permissive attitudes. Especially among health care staff in institutional settings, the institutional regulations, personal moral values, and practical problems of permitting sexual activity among residents may combine to promote a negative attitude even with advanced information about sexuality and aging.

As the value of intimacy for health and well-being is more fully recognized, we expect future groups of elders to be more comfortable about forming intimate relationships. Cohort factors may change the current societal attitudes toward sexuality among the very old. Because so many more adult women are in the workplace, they have more experience with male colleagues. Acceptance of forming new sexual relationships in later life is more likely because many adults have experienced nonmarital sexual relationships in their earlier years of adulthood. The high divorce rate since the mid-1970s means that in the future more women will have had the experience of developing a single lifestyle that includes a network of both male and female friends. With an estimated 1.5 million LGBT adults age 65 and over and a growing openness about same-sex intimate relationships, we see the emergence of niche communities that support the lifestyles of same-sex couples.

FURTHER REFLECTION: *Imagine that you are now 85 years old. Describe the kind of life you hope to be living. What kind of living arrangement, social relationships, and activities would you like to have? What concerns for physical health, safety, intellectual stimulation, and social interaction will you have then? How will you design your life structure to support your needs in these domains?*

The Psychosocial Crisis: Immortality Versus Extinction

OBJECTIVE 5 Define and explain the psychosocial crisis of immortality versus extinction, the central process of social support, the prime adaptive ego quality of confidence, and the core pathology of diffidence.

By the end of later adulthood, most people have developed a point of view about death. Although they may continue to experience anxiety about their impending death, they have found the courage to confront their fears and overcome them. If older adults have achieved integrity, they believe that their life has made sense. This amplifies their confidence about the choices they have made and the goals they have achieved without despair over the failures, missed opportunities, or misfortunes that may have occurred. Thus, elders can accept the end of life and view it as a natural part of the life span. They are capable of distilling wisdom from the events of their lives, including their successes and mistakes.

However, elders are faced with a new challenge—a conflict between the acceptance of death and the intensifying hope for immortality. Having lived longer than their cohort of friends, family members, and even, in some cases, their children, elders struggle to find meaning in their survival. All of us face a certain disbelief about our own mortality. Although we know that death is a certainty, an element of human thought prevents us from facing the full realization of death; we continue to hope for immortality. This quality may be adaptive in that people who have a sense of hope cope with the reality of death better than those who do not (Kesebir, 2011).

Immortality

Elders have a unique appreciation of time. They recognize that there is a finite amount of future time until their death, as well as an unlimited transcendental future time that begins with their death and extends onward into infinity (Boyd & Zimbardo, 1996; Zimbardo & Boyd, 2008). They begin to see themselves as links in a long, fluid chain of historical and biological growth and change. The positive pole of this crisis is a confidence in the continuity of life, a transcendence of death through the development of a symbolic sense of immortality. The achievement of this perspective, which may include the incorporation of transcendental goals such as reuniting with loved ones after death or being released from the limitations of an aging body, may be accompanied with sentiments of joy, which contribute to feelings of well-being, flexibility, and acceptance of the challenges of aging.

A psychosocial sense of **immortality** may be achieved and expressed in many ways (Lifton, 1973). Here, we explore

HUMAN DEVELOPMENT AND DIVERSITY

The Responsibility of Native Hawaiians for Their Ancestors’ Remains

The following narrative describes the psychosocial crisis of immortality versus extinction in the context of the desecration of a native Hawaiian burial site. In fighting to stop the destruction, those involved were reminded of the commitment that the living have for the care and protection of the burial grounds of their ancestors:

> Hawai’i Nei was born December 1988 from the *kaumah a* (heaviness) and *aokanaka* (enlightenment) caused by the archaeological disinterment of over 1,100 ancestral Native Hawaiians from Honokahua, Maui. The ancestral remains were removed over the protests of the Native Hawaiian community in order to build the Ritz Carlton Hotel. The desecration was stopped following a 24-hour vigil at the State Capital. Governor John Waihe’e, a Native Hawaiian, approved of a settlement that returned the ancestral remains to their *one hanau* (birth sands), set aside the reburial site in perpetuity, and moved the hotel inland and away from the ancestral resting place.
>
> In one sense Honokahua represents balance for from this tragedy came enlightenment: the realization by living Native Hawaiians that we were responsible for the care and protection of our ancestors and that cultural protocols needed to be relearned and laws effectively changed to create the empowerment necessary to carry out this important and time-honored responsibility to *malama* (take care) and *kupale* (protect) our ancestors.
>
> Hui Malama I Na Kupuna O Hawai’i Nei members have trained under the direction of Edward and Pualani Kanahele of Hilo in traditional protocols relating to the care of *na iwi kupuna* (ancestral remains). These commitments were undertaken as a form of *aloha* and respect for our own families, ancestors, parents, and children.
>
> Hui Malama I Na Kupuna O Hawai’i Nei has been taught by the Kanahele family about the importance of *pule* (prayer) necessary to *ho’olohe* (listen) to the calling of our ancestors. Through *pule* we request the assistance of *ke akua* and our ancestors to provide us with the tools necessary to conduct our work:
>
> *E homai ka ike, e homai ka ikaika, e homai ka akamai, e homai ka maopop o pono, e homai ka ‘ike papalua, e homai ka man a.*
>
> (Grant us knowledge, grant us strength, grant us intelligence, grant us righteous understanding, grant us visions and avenues of communication, grant us mana.)
>
> Moreover, we have been taught that the relationship between our ancestors and ourselves is one of interdependence—as the living, we have a *kuleana* (responsibility) to care for our *kupuna* (ancestors). In turn, our ancestors respond by protecting us on the spiritual side. Hence, one side cannot completely exist without the other.

Source: Pell (2002), http://huimalama.tripod.com/

Critical Thinking Questions

1. Describe the belief system that connects native Hawaiians and their ancestors. How does this belief system contribute to the resolution of the psychosocial crisis of immortality versus extinction?
2. Predict how the sense of interdependence between the living and the dead might influence the day-to-day behavior of native Hawaiians.
3. Select a culture of interest to you. Investigate and describe the relationship of the living to their ancestors in this culture. Summarize the beliefs, rituals, and actions that reflect this relationship.
4. Analyze the trends of modernization that may explain why Hawaiians have lost touch with the traditional practices associated with the care of ancestral remains. Propose what may be gained by reviving these traditions.

five possible paths toward immortality. First, one may live on through one’s children and grandchildren, sensing a connection and attachment to the future through one’s life and the lives of one’s offspring. This type of immortality can be extended to include devotion to one’s country, social organizations or groups, or humankind.

Second, one may believe in an afterlife, an immortal soul, or a spiritual plane of existence that extends beyond one’s biological life (Pereira, Falsca, & de Sá-Saraiva, 2012). Most religions espouse the concept of a state of harmony with natural forces, so that after death, one endures beyond this earthly life.

Among many indigenous peoples, there is a sacred link between the living and the dead—a responsibility on the part of the living to protect and respect the sacred burial grounds and a responsibility on the part of the dead ancestors to look after the spiritual well-being of the living. This belief is illustrated in the **Human Development and Diversity** box, The Responsibility of Native Hawaiians for Their Ancestors’ Remains.

Third, one may achieve a sense of immortality through creative achievements and their impact on others. Many people find comfort in believing that they are part of a chain of positive influences on the lives of others. This sense of immortality is linked to the achievement of generativity in middle adulthood. Adults who have made a commitment to improving the quality of life for others during middle adulthood are likely to see evidence of this effort by the time they reach elderhood.

> Perhaps it was only in the later years of my practice— I saw the results of my labors in the unfolding lives of my

Blend Images/Shutterstock.com

Through prayer and inspiration, this minister shares her faith and sense of immortality with her congregation.

> patients—that once again I appreciated the value of my link in the chain of life. (Young, 2011)

The bond between an individual and community makes death less final. An African proverb advises that you live as long as someone knows your name. The more embedded you are in your community and the more lives you have touched, the greater the sense of continuity or transcendence.

Fourth, one may develop the notion of participation in the chain of nature. In death, one's body returns to the earth and one's energy is brought forth in a new form.

Fifth, one may achieve a sense of immortality through what Lifton (1973) described as **experiential transcendence**:

> This state is characterized by extraordinary psychic unity and perceptual intensity. But there also occurs … a process of symbolic reordering…. Experiential transcendence includes a feeling of … "continuous present" that can be equated with eternity or with "mythical time." This continuous present is perceived as not only "here and now" but as inseparable from past and future. (p. 10)

The notion of **cosmic transcendence** has been developed further by Lars Tornstam, a Swedish gerontologist, who writes about feelings of cosmic communion with the spirit of the universe, and a redefinition of time, space, life, and death (Tornstam, 2005). This expression of immortality is independent of religion, offspring, or creative achievement. It is an insight derived from moments of rapture or ecstasy in which all that one senses is the power of the moment. In these experiences, the duality of life and death dissolve, and what remains is continuous being.

Extinction

The negative pole of the psychosocial crisis of elderhood is a sense of being bound by the limits of one's life history. In place of a belief in continuous existence and transformation, one views the end of life as an end to motion, attachment, and change. Instead of faith in the ideas of connection and continuity, one experiences a fear of **extinction**—a fear that one's life and its end amount to nothing. Erikson's advice on coping with aging concerns responding to loss and dealing with diminished capacities (see the **Applying Theory and Research to Life** box Erikson on Coping with Aging). It is not difficult to imagine that as a person reflects on the many losses encountered over a long life, there will be periods when it seems that all the effort, striving, hoping, and struggle did not amount to much. In the process of resolving this psychosocial crisis, it is to be expected that people will have at least momentary thoughts that there is nothing more; that the end is truly an end.

The following quotations from a study of very old men suggest the range in sentiment about immortality and extinction (Rosenfeld, 1978, p. 10). About 28 percent of the adults in the study were described as having low morale and made statements such as "I feel I'm a forgotten man. I don't exist anymore…. I don't feel old…. I'm just living out my life." About 25 percent were stoic but not very positive about their condition: "You know you're getting old. You have to put your mind to it and take it as it comes. You can't get out of it. Take it gracefully." Almost half found their lives full and rewarding: "I go home with my cup overflowing. There are so many opportunities to do things for people. These are the happiest days of my life."

Conditions in long-term care facilities may contribute to the sense of extinction for some elders. Imagine living in a facility where the staff consistently mistreats older adults. In one study, incidents of physical abuse, intimidation, and neglect were reported by 44 percent of nursing care residents. Being a victim of violence or being exposed to violent treatment of others in a setting where a person has no way to retaliate or punish the abuser can certainly produce feelings of despair and withdrawal (National Center on Elder Abuse, 2012).

The possibility of ending one's life with a sense of extinction is reflected in the public health concern about suicide among the elderly. In the United States, the highest suicide rate in 2014 was among those 85 years old and older (American Foundation for Suicide Prevention, 2016). Data from the *World Health Organization* provide a basis for describing the incidence of suicide for men and women by age. Men commit suicide at higher rates than women at all ages, and those aged 70 and older have the highest suicide rates. National differences are substantial, with suicide rates higher in the high income as compared to the middle and low income countries (World Health Organization, 2014).

APPLYING THEORY AND RESEARCH TO LIFE

Erikson on Coping with Aging

The Eriksons' advice (Erikson et al., 1986, pp. 332–333) suggests the achievement of experiential transcendence:

> With aging, there are inevitably constant losses—losses of those very close, and friends near and far. Those who have been rich in intimacy also have the most to lose. Recollection is one form of adaptation, but the effort skillfully to form new relationships is adaptive and more rewarding. Old age is necessarily a time of relinquishing—of giving up old friends, old roles, earlier work that was once meaningful, and even possessions that belong to a previous stage of life and are now an impediment to the resiliency and freedom that seem to be requisite for adapting to the unknown challenges that determine the final stage of life.
>
> Trust in interdependence. Give and accept help when it is needed. Old Oedipus well knew that the aged sometimes need three legs; pride can be an asset but not a cane. When frailty takes over, dependence is appropriate, and one has no choice but to trust in the compassion of others and be consistently surprised at how faithful some caretakers can be.
>
> Much living, however, can teach us only how little is known. Accept that essential "not-knowingness" of childhood and with it also that playful curiosity. Growing old can be an interesting adventure and is certainly full of surprises.
>
> One is reminded here of the image Hindu philosophy uses to describe the final letting go—that of merely being. The mother cat picks up in her mouth the kitten, which completely collapses every tension and hangs limp and infinitely trusting in the maternal benevolence. The kitten responds instinctively. We human beings require at least a whole lifetime of practice to do this.

Critical Thinking Questions

1. Critically evaluate the advice provided by Erikson. Would this be good advice to help elders cope with the challenges of aging? If not, what advice would you offer in its place?
2. Given the full course of psychosocial development, speculate about why it may be especially difficult for the elderly to accept help and depend upon others when they need it. What lessons from earlier stages of life might prepare a person to do this?
3. Erikson suggests adopting an outlook of playful "not-knowingness" and adventure. Summarize the cultural, religious, and personal factors that might help a person attain this view of elderhood.
4. Read more about Erik Erikson. What can you find out about how well he was able to accept this advice in the last years of his life?

Relatively few of the elderly in the United States experience a level of discouragement that is implied by the sense of extinction. Among those ages 75 and older, roughly 5 percent reported pervasive feelings of worthlessness or hopelessness (Blackwell, Lucas, & Clarke, 2014). A caution about these data is that elders may be reluctant to report feelings of discouragement or hopelessness.

The Central Process: Social Support

Social support has been defined as the social experiences that lead people to believe that they are cared for and loved, esteemed and valued, and belong to a network of communication and mutual obligation (Cobb, 1979). Social support includes the quantity and interconnectedness or web of social relationships in which a person is embedded, the strength of those ties, the frequency of contact, and the extent to which the support system is perceived as helpful and caring (Bergeman, Plomin, Pedersen, McClearn, & Nesselroade, 1990). It is commonly divided into two different but complementary categories: **socioemotional support**, which refers to expressions of affection, respect, and esteem, and **instrumental support**, which refers to direct assistance, including help with chores, medical care, or transportation. Both types of social support—but especially socioemotional support—contribute to maintaining well-being and fostering the possibility of transcending the physical limitations that accompany aging (Rowe & Kahn, 1998).

The Benefits of Social Support

Social support plays a direct role in promoting health, well-being, and life satisfaction even when a person is not facing a specific stressful situation (Gow et al., 2007; White, Philoogene, Fine, & Sinha, 2009). Because social support involves meaningful social relationships, it reduces isolation. People who have intimate companions in later life have higher levels of life satisfaction. They feel valued and valuable. This kind of social support is likely to be most appreciated when it comes from friends and neighbors—members of the community who are not bound by familial obligation to care about the person, but who do so anyway.

The presence of caring, familiar people provides a flow of affection, information, advice, transportation, and assistance with meals and daily activities, finances, and health care—all critical resources. The support system tends to reduce the impact of stressors and protect people from some of their negative consequences, especially serious illnesses and depression (Krause, 2006).

Tim Hall/Jupiter Images

Social support can contribute to improved health. Jean and Carol exercise together three times a week, talking and laughing as they ride.

Social integration and membership in a meaningful social support network are associated with increased longevity. A high level of social integration is associated with lower mortality rates (Cherry et al., 2013; Rowe & Kahn, 1997). The support system often serves to encourage an older person to maintain health care practices and to seek medical attention when it is needed. Members of the immediate family, close relatives, and friends provide direct care during times of grave illness or loss, encouraging the older person to cope with difficulties and to remain hopeful. Elders are likely to experience declines in physical stamina. They may also have limited financial resources. In order to transcend the limitations of their daily living situations, elders must be convinced that they are embedded in a network of social relationships in which they are valued. But their value cannot be based solely on a physical exchange of goods and services. Rather, it must be founded on an appreciation of the person's dignity and a history of reciprocal caring.

The Dynamics of Social Support

The benefits of receiving social support can be diminished if the recipients adhere to a strong cultural norm for reciprocity. The **norm of reciprocity** implies that you are obligated to return in full value what you receive: "One good turn deserves another." People want and expect to be able to give about the same as or more than they receive. What is given does not have to be identical to what is received, but it has to be perceived as having equal worth. Being in someone's debt may be considered stressful and shameful. In a study of Japanese American elderly people, receiving material support from their family was associated with higher levels of depression and less satisfaction in life, especially for those who had very traditional values about reciprocity. In efforts to mobilize social support to enhance the functioning of the very old, one needs to be sensitive to the context and meaning of that support (Nemoto, 1998).

Most elders continue to see themselves as involved in a reciprocal, supportive relationship with their friends. Feelings of usefulness and competence continue to be important correlates of well-being in later life. Older adults are especially likely to experience positive feelings of life satisfaction when they are able to provide assistance to others at times of significant life transition or need, such as widowhood or the divorce of a child (Davey & Eggebeen, 1998). Even though they are comforted by knowing that support would be available when needed, older adults are likely to experience negative feelings when the support received is more than was needed or when there is no opportunity for them to reciprocate (Liang, Krause, & Bennett, 2001).

Elders may expect to receive more care from their children when they are ill than they can provide in exchange. By shifting to a life-span perspective, however, they can retain a sense of balance by seeing the help they receive now as comparable to the help they gave their children at earlier life stages (Ingersoll-Dayton & Antonucci, 1988). When elders are highly valued, it is not as important that they reciprocate in the exchange of tangible resources. Wisdom, affection, joie de vivre, and a positive model of surviving into old age are intangible resources that are highly valued by members of the very old person's social support network. Being valued may also mean that the person's advice and conversation are adequate exchange for some of the services and assistance provided by family and friends.

Social relationships can include both positive and negative interactions. Within one's social network, positive interactions might include enjoying shared activities, confiding about one's worries, or asking for help when one is ill. Negative interactions might include being taken advantage of, having one's privacy invaded, or being insulted. Sometimes, the same people can be sources of both positive and negative interactions. Not surprisingly, the overall frequency of positive exchanges is related to lower levels of depression. When older adults experience the effects of negative social interactions in one relationship—for example, when they have an argument with their adult child—they can buffer these emotions by having positive interactions with another member of their social network—for example, a friend or spouse (Okun & Keith, 1998).

Many older adults are selective about the people in their social network, striving to interact primarily with people who engage in harmonious interactions. They also take steps to prevent conflict in the relationships they value. For example, they impose certain constraints on their interactions—not criticizing someone in public, respecting others' privacy, and keeping a confidence. These strategies help avoid negative interactions and maximize the satisfaction and stability of their relationships (Sorkin & Rook, 2004).

The Social Support Network

Of course, being an integral part of a social system does not begin in later life. It has its origins in infancy, with the formation of a mutual relationship with a caregiver. Social support systems are extended in childhood and early adolescence through identification with a peer group, and in early and middle adulthood through marriage, childrearing, and relationships with coworkers and adult friends. In later life, family members are usually the primary sources of social support, especially one's spouse, children, and siblings. The quality of the relationship between an adult child and an aging parent has a long history. Clearly, the nature of the support that an aging parent is able to receive or that an adult child is willing to provide is influenced by the feelings of closeness and connection that were fashioned during the childrearing process and also by the child's relationship to the parents during early adulthood years.

In the United States, age is a predictor of the size of the social support network. Younger people have larger social support networks than do older people. This may be true for a variety of reasons. For elder women, the likelihood of living alone is high. After the death of a spouse, men and women must realign their social support systems from among relationships that include their adult children, friends, relatives, neighbors, and new acquaintances in order to satisfy their needs for interaction and companionship. In a study of social relationships following widowhood, women clearly benefited from the social network that existed prior to their husband's death. However, contrary to expectations, efforts to modify this network by renewing old acquaintances or forming new friendships did not help to reduce feelings of depression or loneliness, even 2 years after the loss (Zettel & Rook, 2004).

Elders differ in the composition of their social networks. Whereas some elders rely heavily on close family members, others are closely linked to friends and neighbors, and others find their closest ties in church or community organizations. What is more, each social network component may contribute a unique resource. A sibling might provide emotional support whereas a friend might provide companionship, shared activities, or health-related advice. Elders who are childless or have no surviving children or siblings are especially vulnerable to ending their lives in isolation. In contrast, those who are able to preserve a diverse social network are more likely to be the healthiest, make the most use of appropriate community services, and experience the highest levels of well-being (Antonucci et al., 2001; Bosworth & Schaie, 1997; Litwin, 1997; Litwin & Shiovitz-Ezra, 2011).

Social media are becoming an increasingly valued resource among the elderly for preserving and even expanding their social support network. In a recent national survey conducted by the Pew Research Center, 56 percent of those ages 65 and older said they were regular users of Facebook (Duggan, 2015). Older adults use this resource for a variety of reasons including preserving bonds of friendship with their long-time friends, joining new interest groups, and staying connected with family and loved ones (Rogers, 2016). An especially valued feature of Skype and FaceTime are the real-time interactions that are possible, allowing elders who are not able to visit their family and friends or who have limited mobility to engage in face-to-face conversations.

For many elders, religious participation provides an additional source of social support. Older adults are more likely than younger adults to describe themselves as religious in their beliefs and behavior. Mary, who at age 80 has experienced the deaths of three brothers, her husband, and her daughter-in-law, gives and receives emotional support through her faith:

> I always have a lot of faith. The good Lord has always given me the strength to go on. I was raised to believe and pray when I have problems. I go to Mass every Sunday, and we have other special days when we go to Mass. I'm a Eucharistic minister. God makes me do things to feel better—I serve people and God. I go to buildings to give communion to people who can't get out. (Rowe & Kahn, 1998, p. 164)

Members of religious congregations may provide one another with both emotional and instrumental social support. The place of religion in the lives of the very old is especially significant for African Americans, who are more likely than European Americans to attend religious services regularly, even at advanced ages. They are also more likely to describe themselves as very religious—a characterization that reflects the frequency of their private prayer, their strong emotional commitment, and their reading of religious material. Religious involvement among elderly African Americans is not predicted by income or education. Over time, elders who are active in their religious communities give and receive increasing amounts of emotional support to one another and express increased satisfaction from these church-based relationships (Hayward & Krause, 2013).

Ethnic identity may also become an important vehicle for social support in later life. It can provide sources of nonfamilial support, from a loose network of associations to membership in formal clubs and organizations. Members of an ethnic group may feel a strong sense of community as a result of their shared exposure to past discrimination, a realization of common concerns, and a sense of responsibility to preserve the authenticity of their ethnic identity for future generations. Participation in such a support network may be a way to contribute wisdom gained through life experiences to those who will follow. Insofar as members of ethnic groups have felt marginal in the larger society in the past, their mutual support in later life may protect them from some of the negative stereotypes that the society imposes on the very old.

Involvement in a social support system can be an essential ingredient in the achievement of a sense of immortality. The social support system confirms the value of elders, providing direct evidence of their positive impact on others and embeddedness in their social communities. The social support system of elders usually includes adult children. Positive interactions with them contribute to the sense of living on through one's offspring and their descendants. Interactions with members of the social support system—especially those marked by feelings of warmth, caring, and celebration—may be moments of experiential transcendence for elders. They feel the fullness and joy of existence that transcend physical and material barriers (Sadler et al., 2006).

The Prime Adaptive Ego Quality and the Core Pathology

Confidence

Confidence, as a prime adaptive ego quality, refers to a conscious trust in oneself, an appreciation of one's abilities, and an assurance about the meaningfulness of life. In this definition, one finds the earliest psychosocial crisis of trust versus mistrust integrated with the crisis of integrity versus despair. In elderhood, after a lifetime of facing challenges and experiencing losses and gains, one has a new belief in the validity of one's intuition, a trust in one's worldview, and a continued belief in one's capacity to participate in the world on one's own terms. Confidence is sustained by a stable, supportive social network (Krause, 2007; Lang, Featherman, & Nesselroade, 1997). Older adults who feel they are able to engage in the activities they enjoy and interact with people they value are also more likely to believe that they can adapt to the challenges they face. As a result of their confidence, they are less disrupted by stressful events and more hopeful about being able to find successful solutions in the face of negative events (Pushkar, Arbuckle, Conway, Chaikelson, & Maag, 1997).

Physical health and age, per se, are not the best predictors of confidence. One's perceptions of physical health problems and how one sees oneself in comparison to others may be more important predictors of confidence than any objective measure of health status. Some people view themselves as more impaired and dependent than they actually are; others, who may be suffering from serious illnesses, continue to view their situation with optimism (Ryff, 1995). Similarly, one's perception of the adequacy of social support and its appropriateness in response to one's needs is more important to a sense of confidence than the material value of the resources exchanged (Davey & Eggebeen, 1998).

Over the course of life, psychosocial theory predicts that each individual will confront issues related to the negative poles of the psychosocial crisis of each stage. Finding ways to integrate the negative pole of each stage into an overall positive worldview strengthens and humanizes one's character. Encounters with each negative pole provide a deeper sense of empathy for the suffering of others and a more profound appreciation for the courage that it takes to live out one's life with an open, generous, hopeful outlook. Confidence emerges not because of a life of one success after the next, but out of a sequence of struggles in which creative energy is required to find a positive balance between positive and negative forces (J. M. Erikson, 1988).

Diffidence

Diffidence, the core pathology of elderhood, refers to an inability to act because of overwhelming self-doubt. It is considered one of the basic factors underlying personality disorders (Livesley, Jackson, & Schroeder, 1992). Diffidence is evidenced by an unusual amount of difficulty in making daily decisions without advice and reassurance from others, great reluctance in undertaking projects or becoming involved in activities because of lack of confidence, and fears of being unable to care for oneself, which result in the fear of being alone (American Psychiatric Association, 1994).

Experiences with ageism, being ignored, devalued, or dismissed as irrelevant can promote diffidence. In an era of rapid technological advances and transformations of communities through renovation and renewal, an older person can feel dislocated in space and in relationships, losing the sense of competence about how to navigate in the community. Diffidence can be a product of an earlier form of socialization about "politeness" that no longer guides contemporary social interactions. People call on the phone and, out of politeness, you answer only to find that they want your money, they threaten you with a lawsuit, or they want you to buy some product you don't need. You receive letters in the mail from people you don't know, asking for donations, telling you that you owe money, or that you have been specially selected for some prize. It all turns out to be a sham, leaving you reluctant to answer the next call or open the next piece of mail. Exploitation of the elderly contributes to diffidence—an inability to trust long-learned patterns of courteous behavior.

Diffidence is likely to be associated with hopelessness. Among the elderly, hopelessness is experienced as a negative expectancy about the future and a sense of futility about having an impact on impending events. The combination of hopelessness and depression are strongly associated with suicidal ideation among the elderly (Uncapher, Gallagher-Thompson, Osgood, & Bongar, 1998). Feelings of diffidence can result from increased dependency and loss of control due to physical illness, loss of social support, or marked reduction in the quality of life, or they can be a product of a continuous process of ego pathology, building on the negative resolutions of earlier psychosocial crises. It is clear that in later life, the courage and energy required to remain flexible and adaptive to change must be derived from a depth of ego resources established over the life course. For some of the very old, this precious resource has been eroded and they face the end of life in a state of passivity and doubt.

FURTHER REFLECTION: *Explain what is meant by the psychosocial concept of immortality. Analyze ways that a person's social support system contributes to the resolution of the crisis of immortality versus extinction.*

Evaluate the notion that spirituality becomes a stronger feature of well-being in later life. Why might this be true? What evidence is there to support this idea?

Speculate about how positive resolutions of the crises of generativity versus stagnation and integrity versus despair contribute to the resolution of the crisis of immortality versus extinction.

Applied Topic: Meeting the Needs of the Frail Elderly

OBJECTIVE 6 Apply research and theory to concerns about meeting the needs of the frail elderly.

The goal of providing services or community resources to the frail elderly should be to enhance a realistic level of performance. On the one hand, one should not try to encourage 80-year-olds to live the lives of teenagers or people in their 50s. On the other hand, one should not hold such minimal expectations for the elderly that they are robbed of their autonomy and ability to meet challenges or to strive toward achievable goals. A current focus of research and policy is the extent to which physical frailty in elderhood is treatable or preventable and how to reduce dependency, especially in long-term nursing care.

In 2004, the U.S. Administration on Aging announced an initiative focused on supporting "Seniors Aging in Place" (ageinplace.org) in response to the strong preference among the very old to remain independent. Projects were funded that provided new resources or access to services in the community so that older adults with a wide range of needs and abilities could retain an optimal level of independent functioning. The National Aging in Place Council is a forum whose mission is to encourage professionals and corporations in specific communities to work together to provide the system of community resources that will permit older adults to remain in their homes as long as possible. The council provides suggestions to individuals about how to modify their homes to make them accessible and how to take advantage of community resources and services. It also sponsors innovative collaboration between health care, transportation, and corporate interests to create products and services that will facilitate optimal residential communities for the very old (National Aging in Place Council, 2016).

A. Ramey/PhotoEdit

Because of his problems walking, Caleb was practically homebound. But once his children bought him this motorized chair he was able to enjoy going outdoors, interacting with neighbors, and taking Pebbles for a walk. What other technological inventions help support optimal functioning in elderhood?

Defining Frailty

Frailty has typically been defined in terms of dependency. One common approach is to list any difficulties in the ADLs, including bathing, dressing, transferring from the bed to a chair, using the toilet, and eating. Sometimes, these assessments include walking a short distance because this degree of motor ability is usually required to function independently. Beyond these basic types of self-care, an expanded notion of dependency refers to difficulties in managing IADLs, such as shopping, preparing meals, doing light housework, using transportation, or using the telephone. These tasks, though more complex than the basic ADLs, are essential to maintaining one's daily life without dependence on informal or formal community support services.

Measures of functional limitations often fail to differentiate between what people say they might be able to do (as when completing a survey) and what they actually do in their day-to-day lives. For example, some people may respond to a questionnaire saying that they are able to walk half a mile without help, but they do not ever walk that much. Others may respond that they cannot walk half a mile without help, but in fact they walk several blocks on most days to go to the store near their home. When observed in their natural setting, many older adults use compensatory strategies to overcome some physical impairment or integrate the support of others so they can enact certain functions even though they have serious disabilities. For example, in a sample of women who needed assistance in more than three areas of daily living, more than one fourth still managed to get to church services once a week or more. They did not allow their physical limitations to restrict their role involvement (Glass, 1998; Hayward & Krause, 2013).

Dependency or difficulty in managing ADLs increases markedly after age 85. Many factors combine to produce this dependency. In most postindustrial societies, later adulthood is characterized by a sedentary lifestyle. Estimates suggest that only about 10 percent of older adults are active enough to sustain appropriate levels of muscle strength and cardiovascular capacity. Weakness resulting from disuse combines with certain biological changes, diseases, medications, and malnutrition to produce muscle atrophy, risk of falling, reduced arousal and cognitive capacity, and a gradual decline in confidence in being able to cope with even moderate types of physical exertion.

For many older adults, problems with remaining independent change from time to time. For example, a 20 minute walk each day is known to help support endurance, balance and overall health. However, in the winter, when streets are icy and the weather is cold, a person living in a cold climate may need more help because it is difficult to walk outside. In the event of an acute illness requiring a period of hospitalization, a person may temporarily need support during the post-hospital recovery but does not require long-term institutionalization. Full recovery from a week or two of being bedridden may require additional physical therapy, rebuilding muscle tone and endurance and rebuilding confidence in managing daily tasks. The outcome for the older person depends on the patient, caregiver, and health care system—all sharing expectations for recovery and rehabilitation rather than viewing the person as permanently weakened and destined for prolonged dependency (U.S. Department of Health and Human Services, 2013).

Supporting Optimal Functioning

Optimal functioning is what a person is capable of doing when motivated and well prepared. To support optimal functioning of elderly people, one must accurately assess their limitations. One does not want to take away the supports that help elders sustain their independence or overreact to their physical or intellectual limitations. This tendency, however, is observed in the responses of some adult children to their aging parents. Once children realize that their parents are not functioning at the same high level of competence that they enjoyed previously, the children may move toward a **role reversal**. The children may infantilize or dominate their parents, insisting on taking over all financial matters or attempting to relocate their parents to a more protective housing arrangement. Gradually, some children take away all their parents' decision-making responsibilities.

Although children may view such actions as being in their parents' best interests, they may fail to take their parents' preferences into account. Adult children tend to overemphasize the importance of health and financial considerations for their parents and overlook the significance of familiar housing in preserving the companionship and daily support that are critical to their parents' sense of well-being. Adult children may fail to realize how important decision-making tasks and responsibility for personal care are to the maintenance of their parents' personality structure. In mutually satisfying relationships between adult daughters and their aging mothers, the daughters made sure that their mothers were consistently involved in decisions that affected their lives, even when the mothers were heavily dependent on their daughters for daily care (APA, 2016; Kahana, 1982; Pratt, Jones, Shin, & Walker, 1989).

In many nursing homes, there is a similar tendency to reduce or eliminate expectations of autonomy by failing to give residents responsibilities for planning or performing the activities of daily life. Routine chores such as cooking, cleaning, shopping for groceries, doing laundry, planning meals, answering the phone, paying bills, and writing letters give older adults the sense that life is going along as usual. Replacing these responsibilities with unstructured time may subject very old people to more stress than continuing to expect some forms of regular contribution to daily life. Thus, paid work assignments and structured daily responsibilities are activities that an institutional setting can provide to help maintain a high level of social and intellectual functioning among the residents.

The Eden Alternative (2016), an emerging philosophy in elder care, proposed that loneliness, helplessness, and boredom are the primary sources of suffering in late life. Principles of intervention, training, and care are applied to home and nursing home interventions to address these three concerns. "An Elder-centered community commits to creating a Human Habitat where life revolves around close and continuing contact with people of all ages and abilities, as well as plants and animals. It is these relationships that provide the young and old alike with a pathway to a life worth living." With this principle in mind, the Eden Care approach in nursing home care is to foster meaningful, close relationships; to incorporate unexpected and spontaneous events to prevent boredom; and to give residents responsibilities for decision making and activities depending on their level of functioning. These responsibilities, which might include watering plants, volunteering in a nearby child care center, or reading to other residents, help overcome the negative impact of dependency and institutionalization.

Supporting the optimal functioning of frail elderly people requires an individualized approach. Each person has a unique profile of competencies and limitations. For some, the physical environment presents the greatest barriers to optimal functioning. For example, older adults who are in a wheelchair are likely to experience a fall every so often. However, those who have installed modifications in their home—including widened doorways and halls, railings, and easy-open doors—are less likely to fall than those whose homes have not been modified (Berg, Hines, & Allen, 2002). A person who cannot walk without fear of falling, see well, or grasp objects because of arthritis may need to have modifications in the home that will compensate for these limitations.

The Role of the Community

Most older adults want to remain in their community as long as possible. However, they may not be able to afford to pay for supplemental services. Economic security is more fragile for those 80 and older than for those 65 to 74. Two explanations for this economic vulnerability are the increases in medical and long-term health costs and the fact that Social Security income has not kept up with these increased costs. Fifty-eight percent of older adults are considered economically vulnerable, that is their income is less than two times the supplemental poverty level (Cooper & Gould, 2013; LaPonsie, 2016). Future generations of elders are projected to be at even greater risk since almost one third of those aged 55 and older have no work-related defined retirement plan or retirement savings (National Council on Aging, 2015). Interventions at the community level may be necessary to meet the safety, health, and social needs of elders. Housing, transportation, and health care resources and services are essential elements of a community response. States that invest in these resources are able to reduce the growth in the costs of long-term care expenses for elders (U.S. Department of Health and Human Services, 2013).

In promoting optimal functioning in urban settings, it is important to provide health care settings that are easily accessible for elderly people with limited mobility. As the number of elderly people in the urban centers of the United States increases, health care organizations and providers supported by local, state, and federal governments must be prepared to reach out to the growing population of elderly people (Andrulis, 2000). Many of these people are poor, have physical limitations, and experience psychological barriers such as perceived threat of violence, confusion, fear, and embarrassment over lack of financial resources. As a result, they may be unable or unwilling to leave their immediate environment. Community outreach would have to provide a wide variety of services to a culturally diverse population with special attention to poverty-related concerns.

Community resources that have been found to be useful to elders as they strive to remain in their communities include: transportation resources, educational opportunities, volunteer opportunities, food and nutrition support, housing and home modification services, in-home health care and services, and the creation of social settings where elders can interact including senior centers and adult day service centers. Information and referral services for elders and their caregivers provide access to a diverse array of resources as needs arise and change. Many people are unaware of programs and services for which they are eligible. Community services must include outreach efforts to let elders know about the available resources. The more knowledgeable people are about community resources and services, the longer they are likely to remain living independently in their home (Aging Services Council of Central Texas, 2013; National Institute of Health 2016; Tang & Lee, 2011).

A unique set of coordinated services for elders is described as Project Care, in San Diego, California (County of San Diego, 2016). The project supports frail older adults in living independently and feeling secure. This program has several components:

Are You OK?: A daily telephone call is made to individuals who have signed up for this service. A computer automatically makes the calls at a regularly scheduled time selected by the participant. If the call goes unanswered, volunteers will check to see if the individual is OK.

Gatekeeper: Utility and refuse collection companies provide training for their meter readers and refuse collectors to recognize the warning signs that their customers may be in trouble. These signs include newspapers piling up by the door or garbage not being set out for collection. If a problem is noted, it will be reported to the appropriate authority for follow up.

Minor Home Modification: Volunteers and local business groups are recruited to assist in making minor home repairs for seniors and the disabled. Many of these repairs are related to basic health and safety, such as obtaining grab bars, ramps, handrails, and security lighting.

Safe Return: A nationwide identification system of the Alzheimer's Association that helps authorities locate, identify, and safely return persons with dementia (and other cognitive impairments) who wander and become lost.

Vial of Life: Seniors and adult with disabilities who sign up for this no-cost program will be given a plastic box or a magnetic plastic container that holds specific information on the individual's medical history. Should the paramedics be called in an emergency situation, they use the information in the box to save precious time in providing medical assistance.

You Are Not Alone (YANA): A personalized phone call or home visit by the Senior Volunteer Patrol run by an associated law enforcement in various communities. (County of San Diego, 2016)

In recent years, more elders are choosing to live in urban centers (Abrahms, 2011). Living in areas that are densely populated means access to more markets, specialty shops, and interesting things to do in walking distance. People in New York City are more likely to walk a mile to get to something than people who live in suburban or rural areas. In a shift from earlier views of cities as crime-ridden, disease-promoting, alienating environments, some social scientists are starting to write about urban health advantages. Friendship groups are likely to form in neighborhoods; cities may have bigger, more fully equipped hospitals; and population density can attract more parks, gyms, and recreational facilities. The causal relationship between urban life and health is probably bidirectional. As cities become safer, people with more resources (who generally have greater longevity) want to live there, attracting more of the lifestyle resources that support health.

J&L Images/Getty Images

Many communities are sensitive to the need for informal recreational resources for elderly residents. Bocce ball is a favorite pastime where friends gather to socialize, get a bit of exercise, and engage in friendly competition.

Urban areas are likely to be comprised of "naturally occurring retirement communities" (NORCs), places where over 50 percent of the residents are over age 60. Communities where people of shared interests and needs live near one another allow community members to voice their collective needs and concerns in order to influence the distribution or creation of appropriate resources. At the same time, a community with a certain density of elders provides an efficient approach for locating services that will meet the needs of the residents.

For some elderly adults, the absence of meaningful interpersonal relationships is the greatest barrier to optimal functioning. The role of the informal social support system in meeting the needs of the frail elderly cannot be underestimated. Children, spouses, other relatives, and neighbors are all important sources of help. Within communities, the elderly are themselves likely to provide significant help to age-mates who may be ill, bereaved, or impaired in some way. Most older adults prefer not to have to ask for help. However, they are much better off if they have someone to whom they can turn than if they have no one.

Beyond personal networks of social support, communities have been characterized by different levels of **collective efficacy**, which combines a strong sense of social cohesion with a high level of informal social control (Sampson, Raudenbush, & Earls, 1997). People who live in communities characterized by high collective efficacy are willing to take on important community concerns and to intervene on each other's behalf even if they do not know one another on a personal level. Examples of the impact of collective efficacy include reducing violent victimization, child or elder abuse, and illicit drug trafficking in a neighborhood. Communities that are high in collective efficacy will act to draw on the required resources to attract health care services, create new recreational settings, and improve transportation resources. Communities characterized by collective efficacy can enhance the health and optimal functioning of the frail elderly (Browning & Cagney, 2003).

At age 85, George and his grandchild enjoy some pretense, building a high rise while making sure to be safe with their hard hats. George finds that the time he spends in pretend play fosters his own capacity for creative action.

The Role of Creative Action

People can do a lot for themselves to promote a fulfilling later life. By identifying meaningful goals and coordinating action to achieve these goals, elders can create lives that are both meaningful and manageable (Riediger, Freund, & Baltes, 2005). Elders can alter the structure of their environment to preserve optimal functioning and enhance their sense of well-being. They may move to a warmer climate, to a homogeneous-age community, or to a more modest home or apartment that entails fewer maintenance responsibilities. They may participate in exercise classes or other guided physical activity to improve their strength, endurance, and flexibility. Elders may select some family and friendship relationships that they sustain through frequent interaction, mutual help giving, and shared activities. They may participate in activities in community settings, including churches, senior centers, libraries, and volunteer organizations through which they retain a sense of purpose and social connection. They may decide to focus their interest on a single role that is most important to them. Maintaining a sense of control over important life roles and activities contributes to longevity and well-being. As at earlier ages, elders make choices that direct the course of their lives, provide a sense of meaning, and influence their overall level of adjustment.

In summary, the quality of life for the frail elderly depends on four factors: (1) the specific nature and timing of the health-related limitations that accompany aging; (2) the availability of appropriate resources within the home, family, and community to help compensate for or minimize these limitations; (3) the selective emphasis that the person gives to some life experiences over others as being central to well-being; and (4) the person's motivational orientation to continue to find creative strategies to adapt to change.

FURTHER REFLECTION: *Explain the concept of optimal functioning. Based on what you have read about the developmental tasks and psychosocial crisis of elderhood, what suggestions would you make for enhancing the care of the frail elderly?*

CHAPTER SUMMARY

OBJECTIVE 1 Explain the rationale for identifying elderhood as a unique developmental stage for those of unusual longevity with its own developmental tasks and psychosocial crisis.

Elderhood is a period of new challenges and opportunities that will be faced by an increasing number of people in the years ahead. Those who are 80 years old and older are the fastest growing segment of the U.S. population. Having reached a sense of acceptance of one's death, the task is to find meaning and enjoyment in the "bonus" years of life. This requires ongoing adaptation to changing physical and cognitive capacities, a deepening sense of time and the place of one's life in the history of one's people, and a willingness to find new and flexible solutions to the demands of daily life. This period of life requires ongoing adaptive self-organization.

In attempting to describe the psychosocial development of the very old, we are drawn to concepts that have a strong non-Western philosophical flavor. We have introduced such concepts as psychohistorical perspective, experiential transcendence, immortality, and social support—themes that reflect the need to assume a long-range perspective on life and its meaning.

OBJECTIVE 2 List the physical changes associated with aging, and evaluate the challenges that these changes pose for continued psychosocial well-being.

The quality of daily life for the very old is influenced to a great extent by their physical health. For some, daily activities are restricted by one or more chronic diseases. Nevertheless, the majority of elders continue to live in their own households and perform tasks of daily living independently. The topics addressed in this section include physical fitness, sleep and rest, behavioral slowing, sensory changes, illness, disability, and functional independence. The box on dementia outlines features of the disease and the experiences of caregivers, including both hassles and "uplifts."

OBJECTIVE 3 Describe the concept of a psychohistorical perspective, an altered perspective on time and history that emerges among the long-lived.

The concept of time changes with advanced age so that the continuity of past, present, and future becomes clearer. At age 50, someone who is 20 seems young, but at age 80, someone who is age 50 seems young. People who have lived a long time have had the chance to observe social and historical changes, to adapt to new technologies, and to observe the similarities and differences in the realities they faced growing up as compared to the lives of subsequent generations. This long time perspective brings insights into enduring values of life as well as an appreciation for the process of change.

OBJECTIVE 4 Summarize elements of the lifestyle structure in elderhood, especially living arrangements and gender roles, and analyze the impact of these life structures for continued well-being.

An increasingly wide range of lifestyle alternatives are being invented in elderhood, including opportunities for travel, housing that provides varying levels of care, and patterns of close relationships in which traditional gender roles are modified to take into consideration new capacities and interests. Living arrangements including living alone, aging in place, and living in any one of a variety of styles of "retirement" communities. Each alternative introduces new social and cognitive challenges, and new possibilities for purposeful engagement with community life.

OBJECTIVE 5 Define and explain the psychosocial crisis of immortality versus extinction, the central process of social support, the prime adaptive ego quality of confidence, and the core pathology of diffidence.

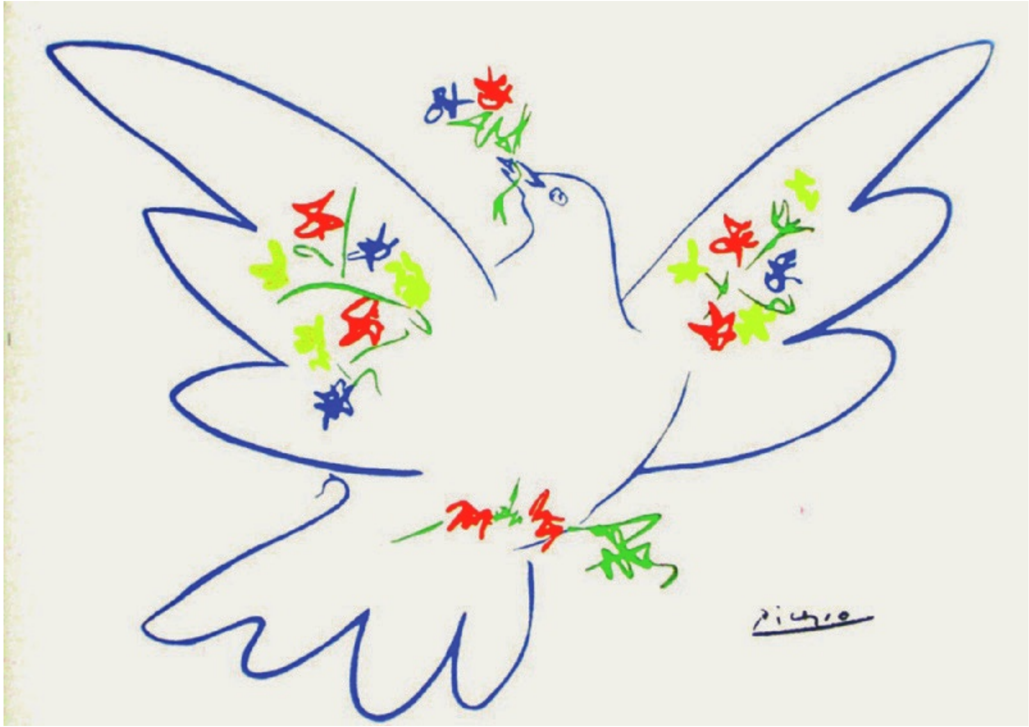
Having lived well beyond their life expectancy, elders face the psychosocial crisis of immortality versus extinction. A key to their quality of life lies in whether they are integrated into effective social support networks. Social support provides help, resources, meaningful social interaction, and a psychological sense of being valued. Elders who survive within a support system can transcend the limitations of their mortality, finding comfort and continuity in their participation in a chain of loving relationships. Those who are isolated, however, are more likely to face the end of their lives bound to the tedium of struggling with their physical limitations and resenting their survival. The themes of purpose and meaning are central to the resolution of this crisis. A positive resolution results in a prime adaptive ego quality of competence; a negative resolution results in diffidence, a pervasive sense of self-doubt.

OBJECTIVE 6 Apply research and theory to concerns about meeting the needs of the frail elderly.

The topic of the care of the frail elderly illustrates the relevance of a biopsychosocial framework. The quality of life for the frail elderly depends on four factors: (1) the specific nature and timing of the health-related limitations that accompany aging; (2) the availability of appropriate resources within the home, family, and community to help compensate for or minimize these limitations; (3) the selective emphasis that the person gives to some life experiences over others as being central to well-being; and (4) the person's motivational orientation to continue to find creative strategies to adapt to change. Elders can guide the direction of their care by the decisions they make, both in earlier periods of life and as they detect new signs of frailty.

CASEBOOK

For additional cases related to this chapter, see "Still Going Strong," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 215–218. This case highlights the importance of living arrangements for the health and well-being of an active 93-year-old woman.



Picasso/Artists Rights Society (ARS), New York

When the dove returned to the ark with an olive branch in its beak, Noah and his family perceived the sign that the period of turmoil was at an end and that life could begin anew. The dove has become a symbol of peace and hope—an image of comfort in a time of grief—providing the sense that rebirth accompanies death.

LEARNING OBJECTIVES

1. Explain how mortality influences psychosocial development.
2. Define the biological state of death, including the distinctions between cardiopulmonary and whole-brain death.
3. Describe factors associated with the process of dying and the modern ideal of a good death.
4. Summarize the role of cultural death-related rituals and their functions.
5. Analyze factors that affect grief and bereavement.

15

UNDERSTANDING DEATH, DYING, AND BEREAVEMENT

Psychosocial Growth Through Bereavement

Chapter Summary

— CASE STUDY Too Late to Die Young —

Harriet McBryde Johnson was diagnosed with muscular dystrophy as a little girl. She has faced a life of surviving the expectation that she would die young.

I'm 3 or 4 years old. I'm sitting on the living room floor, playing with dolls. I look up at the TV and see a little boy. He's sitting on the floor, playing with toy soldiers. Then he's in Little League; he stumbles on his way to first base. He visits a doctor. His parents are sad. He's in a wheelchair. Then a bed. Then I see the toy soldiers. No boy. An unseen narrator says, "Little Billy's toy soldiers have lost their general." It's a commercial for the Muscular Dystrophy Association. As the narrator makes the pitch, a realization comes to me: I will die.

Is it really one of my earliest memories? Or was it manufactured by my imagination? I don't suppose it matters. Either way, it was my truth. I'm a little girl who knows she will die, but I don't say anything. Somehow my mother guesses. "That boy," she says, "has a different kind of muscular dystrophy. Girls don't get it." Maybe, I think, but he looks a lot like me. And pretty soon I see little girls on the telethon and hear that girls too have "killer diseases." I don't know the word, but I figure my mother is in denial.

By the time I am 5, I think of myself as a dying child. I've been sick a lot. There is some discussion before my parents decide to send me to kindergarten. I am glad they do. When I die, I think, I might as well die a kindergartner.

I've just turned 30. I've been lolling in bed for nearly 3 weeks; I say I've strained my neck, but really it's major depression. Just before my birthday my mother had brain surgery. She's come through it beautifully, but I'm terrified to think I could actually outlive my parents. I am further set adrift by the sudden death of the crazy German doctor who nursed me with pea soup and sausages when I refused to go to the hospital with pneumonia. My thoughts race by, but I manage to grab them and take a look. I find that I'm bonkers but rational. I know what's bothering me; my plan to die young hasn't worked out. What do I do now? My thoughts take on the structure of a song with a repeated chorus; it's too late to die young.

I decide to embrace the death sentence. No need to fear it; no need to hasten it. Mortality is something all people share, a unifying force. Every life, whether long or short, is a treasure of infinite value. These things are true, I figure, and it's my job to say so. When I die, I might as well die honest.

CASE ANALYSIS Using What You Know

1. Death is a biological, psychological, and societal reality. Explain how the case illustrates these three interrelated systems.
2. Discuss the challenges of facing an ambiguous dying trajectory for the dying person and for close relatives.
3. Hypothesize about some of the possible reasons for Harriet's depression at age 30.
4. Apply psychosocial theory to account for the life themes that Harriet is facing at age 4; and at age 30.
5. Describe some of Harriet's coping strengths and weaknesses.
6. Imagine that you were Harriet's parents. What would you do to try to prepare Harriet for her life? For her death?

Like bookends, birth and death bracket the story of development. Birth is preceded by a long chain of biological transformations, in which the biochemical thread of DNA is passed from generation to generation. Pregnancy and birth occur in a psychosocial context of relationships, resources, and cultural beliefs and practices. So, too, it is with death. The biological process of dying takes place in a psychosocial context of relationships, resources, and cultural beliefs and practices. Death is accompanied by transformations at the biological, psychological, and societal levels. It is the role of culture and religion to provide narratives or explanations for the transformations of energy that occur in death. Because we cannot empirically test many of these explanations, it is the role of the ego to cope with the unknown aspects of death, to give it personal meaning.

Death is at once a certainty in that all living things die, and a random event, in that the timing of death is unknown. Moreover, whereas through observation, systematic study, and the transmission of knowledge from generation to generation, we have a good idea about the trajectory of development beginning with the prenatal period until death, we have only speculations and belief systems to guide our understanding of what occurs at death and beyond. Thus, death is both inevitable and unknowable.

Thanatology is the field of science that addresses dying, death, and the psychological mechanisms of coping with them. This field includes an analysis of the attitudes toward dying, the meaning of death for individuals and societies, the rituals and practices associated with death, the bereavement process, and the expressions of bereavement across situations and cultures. ●

Mortality and Psychosocial Development

OBJECTIVE 1 Explain how mortality influences psychosocial development.

Psychosocial development focuses on the ongoing interactions between the person and the environment. A person's ability to understand the self and others matures and changes with each psychosocial crisis. At each stage of life, the ego is shaped by the perplexing nature of mortality. In infancy, as one achieves a balance between trust and mistrust, an outlook of hopefulness emerges. This outlook shapes one's orientation toward risk, transitions, and ultimately death. If one has lived a life of hopefulness about the future, this same orientation is likely to extend toward one's beliefs about death—a sense that whatever follows the death of the physical body is going to be good.

In the resolution of the crisis of identity versus role confusion, one confronts the need to impose a sense of meaning on one's life: Where am I going? What do I want out of life? What is my path? Even though one may believe that death is in the distant future, the creation of a personal identity reflects an understanding that since one's life is finite, one's choices should count for something.

The crisis of generativity versus stagnation brings the issue of mortality even more to center stage. Here, one begins to consider the impact of one's life on future generations: What can I do to contribute to the quality of life for others, even after my death? How can I use my resources, talents, and creative abilities to ensure a good future for those who come after me? While still in the throes of caring for children, aging parents, colleagues, and communities, the generative action of middle adults suggests a concern for a time when the ego is not present to nurture and maintain.

Developing a point of view about death is a major developmental task during later adulthood. The resolution of the crisis of integrity versus despair requires recognition that death is increasingly imminent. Integrity is achieved on the shoulders of earlier ego strengths that allow the person to celebrate personal achievements, cherish meaningful relationships, and look with satisfaction at the life thus far lived. The integrity expressed by those in later adulthood—an ability to celebrate life in the face of impending death—is a model for younger generations.

Courtesy of Philip Newman

In older communities it is common to find small family cemeteries where people are buried near their home or farmland. These cemeteries suggest a time when there was a greater intimacy between the living and their ancestors.

Finally, the crisis of immortality versus extinction brings the confidence of continuity. One is ready—though not necessarily eager—to close one door, confident that another will open. In this period, the possibility of death cannot dampen the joy of being and the certainty that one's life is intimately connected with all life.

Over time, direct personal experiences with dying and death have changed. One hundred years ago, most people died in their homes. Many women and infants died in childbirth. As a result, death was experienced by family members who cared for the dying and were present at the death. As you travel through New England, it is common to find small cemeteries near churches and homes where you sense the intimate gathering of families who buried their dead nearby.

With the growth of modern medicine, people who were very ill were taken to hospitals. Those who were dying were removed from the home, and death occurred more in hospitals or nursing homes. Death was sanitized through embalming practices. A culture of death as medical failure emerged, leaving people increasingly alienated from the realities of dying. The discussion of topics related to death and dying became taboo. Children were shielded from experiences with death. Doctors often tried to protect people from the knowledge that they were dying. Once people became terminally ill, they were deprived of the right to have a voice in decisions related to their treatment and the conditions surrounding the end of life (Kastenbaum, 2012).

Beginning with the works of Elisabeth Kübler-Ross (1969/1997, 1983/1997), the needs of the dying person were given a voice again. Concern about allowing people to talk about their fears, to plan for their funeral, and to bring closure to their personal affairs led people to face death more openly and directly. This approach also led to new ways of thinking about the care of the dying. Currently, we have new technologies that allow for the prolongation of life but we continue to face conflicts about how long and under what conditions life should be sustained.

FURTHER REFLECTION: *Explain how the inevitability of death affects your own approach to life. Do you think about death when making important life decisions? Can you give an example?*

Definitions of Death

OBJECTIVE 2 Define the biological state of death, including the distinctions between cardiopulmonary and whole-brain death.

The definition of death has changed. Historically, the criteria for death were lack of a heartbeat and lack of respiration, called **cardiopulmonary death**. This definition was used for hundreds of years. In 1981, the President's Commission for the Ethical Study of Problems in Medicine and Biomedical and Behavioral Research identified eight criteria for the determination of **whole-brain death**:

1. No spontaneous movement in response to any stimuli
2. No spontaneous respirations for at least 1 hour
3. Total lack of responsiveness to even the most painful stimuli

4. No eye movements, blinking, or pupil responses
5. No postural activity, swallowing, yawning, or vocalizing
6. No motor reflexes
7. A flat electroencephalogram (EEG) for at least 10 minutes
8. No change in any of these criteria when they are tested again 24 hours later

In addition to these eight criteria, certain other conditions, such as deep coma, have to be ruled out. Two areas in the brain control different types of life functions: the *brainstem* controls heartbeat and respiration, and the *cortex* controls sensory integration and cognitive function. It is possible for a person's brainstem functions to continue even when there is no cortical functioning. This condition is called **persistent vegetative state**. If you refer back to the list of eight criteria, you can see that the person in this state is not technically dead. When this state occurs, family members, doctors, and sometimes the courts are faced with the difficult decision about whether to let the person die.

In response to the report of the President's Commission, Congress passed the Uniform Determination of Death Act (UDDA). All 50 states and the District of Columbia recognize whole-brain death as the one legal standard. However, the UDDA allows physicians or hospitals to apply the cardiopulmonary definition or the whole-brain death definition, whichever applies first. Despite what we see on television, where a person leans over a body and proclaims, "He's dead," there is ambiguity about whether or not a person is dead.

> First, the diagnosis of brain death may be unreliable. Many patients who meet all the criteria for brain death do not in fact have "irreversible cessation of all functions of the entire brain," because some of the brain stem's homeostatic functions remain, such as temperature control and water and electrolyte balance. To counter this observation, some argue that not all the functions of the brain need to be lost for a patient to be dead, only those that are critical to maintaining integration of the body functions; loss of these critical functions will inevitably lead over hours or days to cardiac arrest, even with continuing intensive life-support. Yet, even though this is often true, the bodies of some patients who meet all the criteria for brain death can survive for many years with all their bodily functions intact except for consciousness and brain stem reflexes. (Sade, 2011, p. 2)

On the one hand, because of the great need for transplantable organs, there is urgency in deciding whether or not a person has died. On the other hand, it is not legal to remove an organ when that removal would cause a person's death. Therefore, the decision whether to harvest organs from people who are experiencing whole-brain death poses a difficult ethical question (DeGrazia, 1998; Sade, 2011).

Advance Directives

Because there are a variety of technologies that can extend life when a person is no longer able to communicate, adults are urged to prepare some form of **advance directive**, such as a living will or durable power of attorney (Doukas & Reichel, 2007). These documents inform a physician or hospital of a person's wishes about life-sustaining procedures in the face of terminal illness or imminent death, and designate someone to act on one's behalf. Through a **living will**, a person can direct physicians or a hospital to withhold life-sustaining procedures and prevent the use of unwanted medical measures when that person is unable to convey those wishes. Some people wear bracelets that say, "living will—do not resuscitate (DNR)" or a medallion stamped NO CODE, which means they do not want to be resuscitated. The **durable power of attorney** authorizes someone to act on behalf of the person regarding financial and property matters and health care decisions. This directive can go into effect when either the agreement is signed or the disability occurs (Hooyman & Kiyak, 2011). One benefit of the living will is that it helps resolve potential conflicts between a dying person's wishes and family members' feelings of obligation to do everything possible to keep the person alive.

Without a "Do Not Resuscitate" directive, when a patient in a hospital stops breathing and has no pulse, a *code blue* team, with 5 to 10 physicians, nurses, and intensive care specialists, is likely to be called in. They initiate mechanical and medical procedures involving shock, IVs, and tubes down the throat aimed at resuscitation for a person who is probably dead (Ofri, 2012). It is possible to register a living will online at www.uslivingwillregistry.com.

The following quotation describes the benefit that accompanied a woman's decision to register her advanced directive with the U.S. Living Will Registry:

> I am very glad I registered my advanced directive. As caregiver to my mother, my father, and my stepmother I cannot express the peace of mind that registering gives. My husband and daughter will never go through the stress of wondering if they are acting according to my wishes. It will be very clear for them. In a way, making my advanced directive is protecting my husband and daughter, even when I am seriously ill. When a loved one is seriously ill is the worst possible time to deal with the subtleties and ramifications of hospital and legal bureaucracies. This will free them from a lot of those worries. (U.S. Living Will Registry, 2010)

One of the more troubling health conditions is Alzheimer's disease, in which there is a gradual loss of mental competence. A decision must be made about when the person is no longer competent and the living will or durable power of attorney will go into effect. Preparation of advance directives requires that people think about the kind of care they want to receive and the conditions under which they want treatment to be withheld. Currently, most Americans do not complete advance directives, and many interventions that are designed to increase completion of advance directives are not effective (Jezewski, Meeker, Sessana, & Finnell, 2007; Kersting, 2004). Even though it is recommended that people consider these issues while they are flourishing, the fact remains that it is difficult for people to face these issues and make decisions about their death.

FURTHER REFLECTION: *Explain the functions of advance directives. How are they related to the various medical conditions that can occur at the end of life?*

The Process of Dying

OBJECTIVE 3 Describe factors associated with the process of dying and the modern ideal of a good death.

People can experience death in many different ways. Their psychological coping strategies differ depending on the context of dying. Kübler-Ross's concept of stages in coming to terms with one's death included: denial, anger and resentment, bargaining, depression and mourning one's death, and acceptance. Although these emotional reactions are all important aspects of understanding how people may cope with the reality of their death, differences in the conditions of death mean that this stage process is not experienced universally. The 10 leading causes of death for 2014 are listed in Table 15.1 (National Center for Health Statistics, 2016c). As you can imagine, the conditions surrounding each of these causes will create different experiences of dying.

Confronting One's Death

In contrast to the notion of stages, some people write about the **dying trajectory** (Lawton, 2001)—that is, the time during which the person's health goes from good to death. Certain illnesses such as some cancers or AIDS result in a gradual decline. Under these conditions, people have more time to acknowledge their death and to plan for it. They may be asked to make a number of decisions about their treatment, in each case weighing the risks or side effects of treatment against the chances of prolonging life. Some people experience unpredictable, sudden death in the midst of a healthy life, as in an automobile accident, by homicide, or a heart attack. This trajectory does not allow the person to confront the reality of death. For some, death involves an ambiguous decline, in which periods of illness may alternate with periods of remission, as in the case of leukemia or muscular dystrophy. These people face a process of learning to live with a disease in which there may be periods of health as well as periods of decline. The person may wrestle with the question of whether they are dying from the illness or living with the illness. The opening case of Harriet McBryde Johnson illustrates the difficulties of making meaning in the face of an ambiguous trajectory.

Table 15.1 Ten Leading Causes of Death and Numbers of Deaths, 2014

Causes of Death	Number of Deaths
All Causes	**2,626,418**
Diseases of the heart	614,348
Malignant neoplasms	591,699
Chronic lower respiratory diseases	147,101
Unintentional injuries	136,053
Cerebrovascular diseases	133,103
Alzheimer's disease	93,541
Diabetes mellitus	76,488
Influenza and pneumonia	55,227
Nephritis, nephrotic syndrome, and nephrosis	48,146
Suicide	42,773

Source: CDC. (2015). Health United States, 2015. Table 19. Leading causes of death and numbers of deaths: United States, 1980 and 2014.

The dying process may bring a high **degree of suffering**, including shortness of breath, inability to eat, limited mobility, and pain. In some instances, this suffering can be alleviated with medications, but in some cases it grows worse. Health care providers and family members often express great dissatisfaction with these end-of-life conditions for the dying person and the surviving loved ones.

The dying process may be conceptualized in different ways depending on the *age* of the dying person. The primary cause of death differs for people of various age groups, creating different contexts for dying. Children and adolescents are most likely to die from accidents including injuries due to fire and auto accidents, or abuse. In middle adulthood, cancer, heart disease, and liver disease are common causes of death, along with unintentional accidents and suicide. Older adults are most likely to die of the complications from chronic diseases, such as heart disease, diabetes, pneumonia, or cancer (National Center for Health Statistics, 2016c).

People of different ages have differing cognitive abilities, psychological coping mechanisms, and views of the future that they bring to the tasks of preparing for death. Kübler-Ross reported the following poem that was written by Mike, a teenage boy, to his parents on the day of his death:

> The time has come,
> My job is done.
> Now it's time for another one
> The gates will open, open soon
> I now will go.
> See you soon.
> Time, time will never stop
> Everlasting time
> Love is eternal
> Forevermore love
> I will always love you. (Kübler-Ross, 1983, p. 189)

Because of the nature of his illness, Mike had time to prepare for his death. His mother reports that he taped messages to his family and friends, helped plan his funeral, and gave a few things away before he died. At this age, Mike appears to have a hopeful view about an everlasting life. He is able to conceptualize dying as a transition that allows some continuity between the life he had and the life he is going to have. He also sees a future in which he will be reunited with the other loved ones in his life before too long. Another teenager, John, who was terminally ill, stated that before he died he wanted two things: to own a van and to make love to a woman (Kübler-Ross, 1983, p. 184). Here we see a youthful approach to the dying process. John's goals are more fun loving and pragmatic, whereas Mike's approach is more spiritual and interpersonal.

Ray Bradbury provided a portrait of a great-grandmother's approach to her own death. At 90, Great-Grandma told her children and grandchildren:

> I don't want any Halloween parties here tomorrow.
> Don't want anyone saying anything sweet about me;
> I said it all in my time and my pride. I've tasted every
> victual and danced every dance; now there's one last tart
> I haven't bit on, one tune I haven't whistled. But I'm not
> afraid. I'm truly curious. Death won't get a crumb by
> my mouth I won't keep and savor. So don't you worry
> over me. Now, all of you go, and let me find my sleep.
> (Bradbury, 1957/1964, pp. 140–141)

In this case, Great-Grandma reassures her children that she is ready—that she has experienced a full life and sees death as the next dance. In addition to the way death is perceived by the dying, the death will be perceived and conceptualized differently by caregivers. The death of a child or adolescent may be seen as quite tragic in the minds and hearts of parents and friends; the death of an older person may be seen as the natural close to a full life. In some cultures, the death of an elder is especially painful, as it results in the loss of wisdom and guidance for younger generations. In other cultures, the death of a child is especially tragic, because it results in the loss of promise and potential for the future.

The Good Death

Professionals who are responsible for the care of the dying have begun to define the characteristics of a good death or dying well. Certain themes stand out across various groups (Emanuel & Emanuel, 1998; Kehl, 2006; Meier et al., 2016; Webb, 1997). One British group offered the following 12 principles of a good death (Smith, 2000):

- To know when death is coming, and to understand what can be expected
- To be able to retain control of what happens
- To be afforded dignity and privacy
- To have control over pain relief and other symptom control
- To have choice and control over where death occurs (at home or elsewhere)
- To have access to information and expertise of whatever kind is necessary
- To have access to any spiritual or emotional support required
- To have access to hospice care in any location, not only in the hospital
- To have control over who is present and who shares the end
- To be able to issue advanced directives which ensure wishes are respected
- To have time to say good-bye and control over other aspects of timing
- To be able to leave when it is time to go and not to have life prolonged pointlessly

Research on perspectives about dying find that the definition of a **good death** is highly individual, shaped by the context of dying and changing over the course of the illness. The ideals of a good death were studied by asking recent widows and widowers to rate their spouses' end-of-life experiences along the following dimensions (Carr, 2003):

- Spouse was at peace with the idea of dying
- Spouse was aware of the impending death
- Respondent and spouse discussed the death
- Respondent was with spouse at the moment of death
- Spouse led a full life
- Spouse was not in pain
- Spouse did not receive negligent care

These dimensions represent concrete evidence of what people perceive to be a good death. Of all these features, the greatest psychological distress for the survivor was associated with seeing the spouse in great pain at the end of life. Although roughly 70 percent of Americans say they would prefer to die at home, about 75 percent actually die in a hospital, many undergoing painful medical interventions in attempts to prolong life (Cloud, 2000).

In a study of what patients, family members, and their health care professionals were concerned about in preparing for the end of life, the following issues were highlighted: naming someone to make decisions, knowing what to expect about one's physical condition, having one's financial affairs in order, having one's treatment preferences in writing, and knowing that one's physician is comfortable talking about death. Dying patients were also concerned about planning their funeral (Steinhauser et al., 2001).

How well are people's needs being met at the end of their lives? Researchers addressed this question through a telephone interview with family members or close associates of more than 1,500 people who had died in the previous 9 to 15 months (Teno et al., 2004). The focus was on the location where people die and the quality of care received by the person in the last 48 hours of life. Two thirds of the deceased had been in a hospital or nursing home in the last 48 hours of life. Of the one third who died at home, 38 percent had no nursing services, 12 percent had some home nursing services, and 50 percent had home hospice services. Over 70 percent of those whose loved ones received hospice care rated that care as excellent. Fewer than 50 percent of those whose loved ones died in a hospital, nursing home, or at home with home nursing services rated their care as excellent. With the exception of those receiving hospice care, many of the bereaved felt that their loved ones did not receive the pain relief, respect, or emotional support they needed in the 2 days before their death.

Two different paths to achieving a good death among people who are in a slow, painful death trajectory include hospice care and euthanasia.

Hospice Care

Hospice care is an integrated system of medicine, nursing, counseling, and spiritual care for the dying person and their family. Its goal is to achieve the highest possible quality of life for the dying

iStockphoto.com/SilviaJansen

The quality of a good death is fostered when caregivers are able to minimize discomfort and support the patient's positive emotional state.

person and the family, alleviating physical and emotional pain to the highest degree possible while supporting family strengths to cope with the process of dying, loss of the loved one, and long-term bereavement (Bruera & Yennurajalingam, 2011; Knee, 2010). Hospice care can take place in a hospice setting or at home.

The Hospice Education Institute (2001) offers the following goals for high-quality end-of-life care:

- Promote relief from pain
- Integrate the psychological and spiritual aspects of patient care
- Offer a support system to help patients live as actively as possible until death
- Help the family cope during the patient's illness and their own bereavement

Hospice care differs from traditional hospital care in that the focus is on enhancing the quality of life for the dying person and the loved ones rather than on treating the disease or intervening to delay the end of life. The first role of hospice care is to relieve the person's pain and suffering through medical, physical, psychological, and spiritual means. Dying patients are encouraged to take an active role in as many aspects of their end-of-life care as their cognitive functioning and health permit. They are supported in talking about their death and interacting with their family. Hospice care has many advantages for those with a terminal illness. It prevents the experience of dying alone for those who do not have family and friends nearby. It allows the person to die in a more natural, familiar setting rather than in a hospital or nursing home. It offers emotional, spiritual, and physical comfort, helping more people experience a good death.

Mary Wasacz is a spiritual care coordinator who works for the Hospice and Palliative Care of Westchester in New York.

> Her job is to care for the spiritual lives of the dying and those who love them. She visits their homes.… She helps (patients) face their relationship with God, address their doubts, come to terms with their religious shortcomings, hold tighter to their faith (whether it's rich or flickering) and prepare for death.… "This is sacred ground," says Wasacz. "It is such a sad time, but a privilege to be there, on this journey with them. It can be uplifting. What I do is facilitate peace." (Stern, 2007)

People come to the role of hospice work through many paths. Mary Wasacz is a devout Roman Catholic and Eucharistic minister (she has been specially trained by the clergy to administer the sacrament of the Eucharist or communion). She does not advocate her religion, or any particular religious orientation as a spiritual care coordinator, but her own faith helps her reassure people as they deal with their many fears and doubts. In contrast, Loretta Downs came to her role as a Hospice Partners volunteer patient companion after having experienced the death of many close friends who died of AIDS. She approaches her role in hospice through the lens of yoga training.

> Hospice is … a blanket of hope. It is a safe haven in which a team of specialists form a cocoon around the dying one and guide him or her through physical transformation while encouraging spiritual healing along the way. I am to be present in silence as well as in laughter and tears. I am to encourage all the appropriate activity and behavior my patients are able to perform while I create a space for them to engage in spiritual healing.… I am to be open to learn how to die myself. Now my patients and their families are my teachers. (Downs, 2004)

Angela Morrow described a third path, from intensive care nursing to hospice:

> I began my nursing career in an intensive care unit. The majority of deaths I witnessed there involved patients, most of whom were elderly, undergoing painful tests and treatments.… I'll never forget the 90-year-old male patient who had terminal cancer and was admitted to the intensive care unit with severe breathing problems. We had to place a tube down his throat to help him breathe and inserted several IV lines to give him medicine. His hands were tied to the bed and he was given medication to put him into a coma-like state. Then his heart stopped. We spent a long time trying to revive him and with every chest compression I gave him, I thought, "What are we doing? Why are we doing this?"
>
> Now that I'm working in hospice, I have the pleasure of helping my patients achieve a "good death," one that is in accordance with their goals and priorities. (Morrow, 2008)

The story of the hospice movement illustrates how many factors converge to create a new set of policies and practices. The concept of the hospice as a setting for the care of terminally ill patients is attributed to Dr. Cicely Saunders, who founded St. Christopher's Hospice in London in 1967. In 1963, she gave a talk at Yale University about her work with terminally ill cancer patients and their families, illustrating the many ways in which patients benefited from an integrated approach to care. Following her talk, Florence Wald, the Dean of the Yale School of Nursing, invited Dr. Saunders to be a visiting faculty member for a semester. Subsequently, in 1968, Dr. Wald took a sabbatical and spent time with Dr. Saunders at St. Christopher's. These two health care leaders were supported in their efforts to create hospice settings in the United States by the publication of Dr. Kübler-Ross' book, *On Death and Dying*, in 1969. In 1972, the U.S. Senate Special Committee on Aging heard testimony from Dr. Kübler-Ross about the negative impact of institutionalizing and isolating the dying. Between 1978 and 1982, several demonstration programs to explore the benefits of hospice care were funded by federal agencies and private foundations. As a result, the U.S. Congress included hospice care as a reimbursable Medicare benefit in 1982—a provision that became permanent in 1986.

Since that time, Congress has increased the level of reimbursement for hospice care, included hospice care as part of veterans' benefits, and included hospice care in the review of efforts to reduce waste and abuse in the Medicare and Medicaid systems. Clear guidelines have been established for the range and quality of services that hospices must offer in order to receive Medicare reimbursements, and an increasing range of educational and training programs have emerged to provide interdisciplinary training for professionals working in hospice and end-of-life care settings. In 1999, the U.S. Postal Service issued the Hospice Care Commemorative Stamp, marking the recognition of this successful model as part of the continuum of health care (National Hospice and Palliative Care Organization, 2005).

To take advantage of hospice through Medicare, one must make a decision to forgo any further life-saving or life-prolonging treatments. A physician must also submit certification that the person is terminally ill, with 6 months or less to live. This provision is one of the current limitations in the use of hospice care within the Medicare system. In 2014, an estimated 1.3 million people received hospice services, 77 percent of whom were age 75 or older (Harris-Kojetin et al. 2016). In advanced stages of Alzheimer's disease and other forms of dementia, the demands on caregivers can be intense, but survival can be prolonged beyond 6 months. As a result, only a small percentage of those with Medicare hospice coverage are patients with Alzheimer's disease (Kersting, 2004). To learn more about hospice care, you can visit the website of the National Hospice and Palliative Care Organization.

Euthanasia

Euthanasia is the practice of ending someone's life for reasons of mercy. In comparison to hospice care, euthanasia is considered when pain medication is ineffective in reducing suffering, when a person is in a persistent vegetative state being kept alive by mechanical equipment, or when a person is in the final stages of a terminal illness. Euthanasia generally involves hastening the end of life by allowing people to have control over their death (Kastenbaum 2012).

Passive Euthanasia. Imagine that a person in the late stages of Alzheimer's disease is diagnosed as having cancer. Should treatments including surgery, chemotherapy, and radiation be administered to prolong the life of someone who is already near death? Passive euthanasia refers to withholding treatment or removing life-sustaining nourishment and breathing aids. The result is that death occurs more quickly than if these procedures were continued. Through a living will, a person can make wishes known to others, including the hospital or care center, physicians, and family members or legal representatives. Through the durable power of attorney, a person assigns life-prolonging or life-ending decision making to a representative. Thus, by refusing treatment or by granting discretion to others to end extraordinary treatment, individuals may hasten their own death. In the preceding example of a person suffering from dementia, if the person had a living will or durable power of attorney, a decision could be made by someone else to withhold treatment for the cancer, if the person is no longer capable of decision making.

Active Euthanasia. Activities designed to end a person's life are referred to as active euthanasia. There are several ways in which this may happen. **Mercy killing** involves actively taking a person's life. This is sometimes done in order to end a person's suffering. In our society, this is considered to be murder. States vary widely on whether the killer will be prosecuted for this act and whether juries will be willing to convict. In a Michigan case of a nurse who ended the lives of more than 20 patients at the Ann Arbor VA hospital, the jury found the nurse to be guilty of murder and sentenced her to life imprisonment. In a California case of a spouse who strangled her husband to end his suffering because she could not help him any longer, the state decided not to prosecute.

Physician-assisted suicide (PAS) involves either the administration of a lethal dose of some medication by a physician or arranging for a terminally ill patient to administer his or her own lethal dose of medication using a suicide machine. This is a controversial procedure. In 1994, Oregon passed a Death with Dignity Act (ODDA) allowing individuals who are terminally ill to request a prescription from their physician for a lethal dose of medication. According to that act, doctors would be allowed to help patients commit suicide by prescribing a lethal dose of medication under the following conditions (Oregon Health Services, 2010a):

1. Patients must be 18 years old or over and be residents of the state of Oregon.
2. Patients have been informed that they have a terminal disease and that they have less than 6 months to live; this must be confirmed by a second opinion.
3. The patient must make a written request for the lethal medication twice, at least 15 days apart, in the presence of two witnesses.
4. There must be an evaluation to determine that the person is capable of making an informed decision, that there is no psychological disorder that would impair the ability to make the decision, and that the person is not suffering from depression.

5. The patient must be informed of the risks and possible results of taking the medication and counseled as to feasible alternatives such as hospice or palliative care.
6. The patient must be advised to have someone present at the time of taking the medication and urged not to take the medication in public.
7. The patient is advised of the right to rescind the request at any time.

Technological innovations allow physicians to keep a person alive with the hope of saving them. These advances raise many ethical questions about conditions under which life should be sustained and treatment continued. Under what conditions do you think treatment should be terminated?

In 1997, the U.S. Supreme Court ruled that there is no constitutional right to physician-assisted suicide, leaving the issue up to the states. They did not overturn the Oregon law. In 1997, Oregon voters affirmed the decision to allow physician-assisted suicide by passing the measure again. In 2009, 95 people received prescriptions, and 53 took the medication. The most frequently mentioned end-of-life concerns were loss of autonomy (96.6 percent), loss of dignity (91.5 percent), and decreasing ability to participate in activities that made life enjoyable (86.4 percent) (Oregon Human Services, 2010b).

How common are these measures? In the United States, legislation regarding Death with Dignity has been passed in four states—California, Washington, Oregon, and Vermont—and has been approved through court ruling in Montana (Death with Dignity, 2016). In all other states, assisted suicide and active euthanasia are illegal, which makes it difficult to know how often these strategies are used. A study of the use of PAS in the state of Washington found that over a 3-year period, 255 people received lethal prescriptions from a physician. This is in the context of 50,000 deaths per year in that state (Gordon, 2013). Although the provision is used infrequently, the people who requested it typically had a terminal form of cancer and were grateful that this alternative was open to them.

PAS is legal in several European countries including Belgium, Germany, Luxembourg, The Netherlands, and Switzerland, and it has also been recently approved in Canada (Lewis, 2015). In a study in The Netherlands, which has accurate records about requests for PAS, Wolf (1996) found that 38 percent of all deaths involved some kind of medical decision. Of these, 18 percent were the result of passive euthanasia where treatment was not provided, and 18 percent involved hastening death by providing pain medication or other care that led to death occurring more quickly than it might have by not using these treatments. Only about 2 percent of all cases involved the administration of a lethal drug or physician-assisted suicide. Thus, even in a country where assisted suicide is permitted, it is approached cautiously and used sparingly.

Ethical Issues at the End of Life

Ethical principles focus on standards of right and wrong, especially as they govern areas of moral and professional responsibility. Ethical issues surrounding end-of-life decisions bring to mind the applied topic of abortion that was discussed in chapter 4. One might view abortion as a special case of decisions about ending life. End-of-life decisions are relevant not only for elderly people; they may also be addressed when parents decide to limit treatment for a terminally ill child, when family members decide to remove life support for an adult who is in a vegetative state, or when a person seeks assisted suicide in order to avoid a decline into an immobile or helpless state. The matter is made even more complex because decisions about ending life conflict with the commitment of the medical profession to prolong life. As a result of many new technologies, medications, and genetic interventions, there are ongoing innovations that may be effective in slowing the progression of a disease or sustaining life even if the condition cannot be cured.

Public opinion about the acceptability of physicians helping patients end their lives depends on how the question is framed. The following question has been asked in polls from 1947 to 2016: "When a person has a disease that cannot be cured, do you think doctors should be allowed by law to end the patient's life by some painless means if the patient and his family request it?" In 1947, 37 percent of respondents said yes; in 2016, 69 percent said yes. Clearly, the public has a more accepting view of involving doctors in euthanasia today than in the past (Swift, 2016). The range of techniques that are available to prolong life has expanded profoundly since 1947. One consequence is the need for a new level of decision making among those who are dying and their families about the point at which medical treatment should be discontinued.

In contrast to PAS, some dying patients exercise a right to voluntarily refuse food and fluids as a way to hasten death. In interviews with 20 hospice workers, both nurses and social workers, 33 different cases were described where people wanted to hasten their death (Harvath et al., 2006). Two thirds sought PAS; one third chose refusal of food and fluids. The hospice workers who were interviewed perceived these two paths as substantially different with different ethical considerations. Voluntary refusal of food and fluids was seen as "letting go of life" and most hospice workers viewed it as an expression of a dying person's autonomy.

> I don't have any dilemmas or ethical issues with a person not eating or drinking. It's a part of hospice that people have a right to determine what they will and will not do, how they want to die. There's a big difference between that and somebody taking (a lethal dose of) medicine. Nobody makes a decision to tell a person not to eat or drink. (Harvath et al., 2006, p. 209)

Despite public opinion supporting PAS, issues around voluntarily ending one's life continue to be a matter of ethical controversy (Fraser & Walters, 2001; Walker, 2001). In the recent Gallup poll where a large majority favor PAS, only 53 percent say that they consider it morally acceptable, and 51 percent say they would consider ending their own lives if they were facing an incurable disease or living in great pain (Swift, 2016). Those who support PAS argue that it respects the individual liberties and personal autonomy of those who are terminally ill but competent to make an informed decision about the end of life. It is also a compassionate response to help end suffering. Finally legalizing PAS would open the possibility for more reasoned, full discussion of alternatives between patients and their physicians. At present, these conversations are taking place covertly, without full access to information about alternatives.

Opponents of PAS argue that legalizing assisted suicide might put undue pressure on elderly people to end their lives rather than be a burden to their families or to use scarce financial resources for end-of-life care. For those who have struggled to have access to quality health care during their adult lives, there is great mistrust about giving someone the right to withhold care or accelerate their death. Other opponents suggest that permitting those who are terminally ill to choose death would be one step toward a process of killing people who have mental disabilities or are born with serious defects that affect their quality of life. Some contend that the dying person who is in a great deal of pain may be depressed and lose sight of the possibilities for medical treatments that could improve their medical condition. With effective counseling, the person might be less desperate about the suffering and find ways to achieve a new sense of closeness with loved ones. Finally, there are those who feel that allowing someone to decide to end his or her own life is a violation of their religious values and is unacceptable regardless of the conditions faced by the ill person.

FURTHER REFLECTION: *Explain the concept of the "good death." How does culture influence the way people think about ideal or optimal end- of-life experiences?*

Critically evaluate the proposition that people should have as much control as possible over the conditions surrounding their death and dying.

Death-Related Rituals

OBJECTIVE 4 Summarize the role of cultural death-related rituals and their functions.

Death is a powerful change of state that has mysterious qualities. Typically, it is accompanied by a range of symbolic rituals. These rituals address at least three critical aspects of death: (1) how to treat the physical body—the corpse—in an appropriate way (2) how to address the fate of the spiritual aspect of the person—the soul, and (3) how to meet the emotional needs of the survivors and the needs of the society as a whole. Across cultures, people feel a strong need to carry out funeral rituals for the burial or cremation of the dead. Rituals have the advantage of offering a prescribed set of practices at a time when people may be too distressed to make complex decisions. Over one's life span, prior attendance and participation in funeral rituals provide some comfort and familiarity that may help reduce the distress when a loved one dies.

Funeral rituals allow survivors to say good-bye to their loved one, honor the dead person, and begin to detach themselves from the dead person. The concrete evidence of the body proves beyond a doubt to survivors that the person is dead. This helps break down natural tendencies to want to deny the loss. When there is no body, as sometimes happens in natural disasters, mass killings, and war, survivors may be overcome by distress and anxiety caused by uncertainty. Under these conditions, communities sometimes create memorial services or monuments to symbolically bury their dead (Boss, 2002a). The following section provides examples of traditional customs, and community practices in the context of the death.

Care of the Body

Most funeral preparations include specific practices for caring for the corpse. Often, the corpse is washed and wrapped in a funeral shroud or cloth. Muslims wash the body in warm water and soap and, finally, with a scented water. Among Native Americans, a powdery substance made of corn is used to cover the dead person's face. Among Protestants and Catholics in Europe and the United States, the body is usually washed, embalmed, and dressed in clothes selected by the family. Often, cosmetics are applied to make the person look as if he or she is sleeping. The corpse is placed in a casket and laid out for viewing. According to Jewish tradition, the deceased person is to be attended by a guardian, usually a family member or close friend, for the period from death to burial. The body is to be cleansed according to specific rituals by a specially trained person or a Jewish funeral director.

Cultures have different practices concerning how quickly the body is to be disposed of after death. In most Protestant and Catholic families, there is a 1- to 3-day viewing period after death, when family and friends come to the funeral home to see the body and pay respects to family members. This precedes the actual funeral service and burial. In contrast, among Islamic families, the body is prepared by family members when possible, men

Yadid Levy/Alamy Stock Photo

In India, the body of a dead woman is prepared for cremation as family members, friends, and members of the community look on.

caring for the body of men and women for the body of women. The burial is expected to take place as soon as possible after the death, preferably within 24 hours (Aisha, 2013). In Japan, Buddhists allow 3 days to pass before the body is burned. On the first day, a priest comes to the home and recites a prayer called a *sutra*. On the second day, the family members burn incense sticks before the family altar. On the third day, the body is burned at a funeral hall, and the ashes are brought back to the house and then taken to the cemetery.

Care of the Spirit

Most cultures believe that there is a spiritual component of a person's being that is not destroyed as the body decomposes or burns. Certain ritual practices are designed to help the spirit make a transition to whatever existence the culture believes takes place after death. According to a Gallup Poll taken in 2016, 71 percent of Americans believe in heaven and 14 percent say they are not sure (Newport, 2016). The concept of heaven, whether it is viewed as a beautiful garden or a perfect, golden city, is typically conceptualized as a paradise of safety and abundance where some form of pleasant existence continues after death (Miller, 2010).

The pathway to heaven depends on one's religious and cultural beliefs. For example, in the Roman Catholic religion, the Last Rites, or Viaticum (which in Latin refers to provision for the journey), is a ritual that is carried out at the end of life or in instances of serious illness. The ritual is a celebration of faith; a prayer for God to deliver the person from the illness of body, mind, and spirit; and a process of absolving the person of sins in preparation for life after death in a state of grace. As part of the ritual, the person confesses sins, takes communion, and prays with the priest or Eucharistic minister, reciting a set of familiar prayers and blessing (beliefnet, 2007).

Preparation of the spirit or soul may be achieved by reciting specific prayers or burying the person with possessions that may be useful in the afterlife. Singing, dancing, and playing musical instruments are sometimes used to speed the departed spirit on its way to the next life. Hindus believe that at death, the spirit leaves the body and enters a small flame that is lit next to the body. The spirit remains in the home because of attachments to family and possessions. The body is cremated, and there is a period of prayers in the person's home that lasts for 12 days. On the 10th day, the flame with the spirit is taken to the sea. Placing the flame in the sea is a signal to the spirit to leave the attachments of the earthly life and begin the transition to the afterlife.

The Navajo believe that the dead person will need certain resources in the afterlife. The dead are often buried with an extra set of clothes, food, water, and other items that may be of value in the afterworld. The Navajo believe that everything a person creates has some part of the person's spirit in it. As a result, at death, many of the artifacts a person made, such as pottery or blankets, are cracked or torn in order to release the person's spirit (Santillanes, 1997).

Many societies also observe rituals in the years following the death to nurture and respect the spirit of the ancestor and establish a link between the living and the departed. In Estonia, it is thought that there is a day each year when the dead return to their home for a visit. Rooms are cleaned, and food is laid out for a banquet. This is to preserve and strengthen relationships between the living and the souls of the dead. In Mexican tradition, The Day of the Dead, or All Souls Day, November 2, is a similar ritual. Many families believe that the souls of deceased loved ones return on this day to comfort and advise their family members. Many Japanese families visit the cemetery four times each year. They also have small altars in their homes, where they pray to their ancestors. They believe that the ancestors are always with them, guiding their lives and providing protection. In America, many people of different cultures visit the cemetery for periods of reflection, solitude, and discussion with dead relatives. Practices of leaving flowers and wreaths at the gravesite are expressions of respect.

Care of the Surviving Family, Friends, and Community

In addition to addressing the treatment of the body and soul, death rituals are important for helping the people who remain to cope with their grief and reorient their lives in a world without the person who died. These rituals also allow the society to elaborate the meaning of death and decrease the ambiguity surrounding death. Most cultures have funerals for the dead. These funerals involve a gathering of family, friends, and spiritual leaders to carry out the rites for the dead person, provide a social context for expressions of grief, celebrate the life of the person who died, and begin the process of social support for those who remain. Depending on cultural custom, these gatherings may occur before or after the burial or cremation. Funerals or memorial services provide a transition period surrounding death when people often have difficulty believing that the loved one has really died.

Among Africans who have migrated to the United States in recent years, a complex set of funeral rituals are observed that help mark the status of the deceased and to reaffirm traditional customs of the African community. The wake may last many days as mourners gather from distant locations. The entire community contributes money to cover the costs of food, burial expenses, and the family's support during the period of mourning. The funeral begins with drumming, singing, and dancing, which continue when the funeral procession moves to the burial site or the airport if the person is returned to Africa to be buried with his or her ancestors. The more important the social position of the deceased, the more elaborate the funeral (Hazell, 1997).

In the Jewish tradition, the period of mourning is prescribed in some detail, taking the bereaved from the days immediately following the funeral through the first year and annually thereafter. Special focus is given to the practices expected of children on the death of their parents. This may be related to the importance placed on the fifth commandment to honor one's father and mother. Upon returning to the home after the burial, the family members light a *shiva* (shiva means 7) candle, which represents the everlasting soul of the deceased. They then begin 7 days of mourning. This is a time when family members stay at home and focus their attention on their grief and recollections of the deceased. Friends usually come by to visit, but no business is transacted. It is a solemn time, when luxuries and recreation are set aside. The Kaddish, a prayer that affirms life and faith in God, is recited daily. On the seventh day, the *shiva* candle is extinguished and the family members take a walk outside, symbolically escorting the loved one's soul out of the house and indicating that the family is strong enough to carry on their lives. The period of mourning typically lasts 12 months for those who have lost a parent and is marked by the unveiling of the tombstone or grave marker. After that time, children note the anniversary of their parents' death by lighting a *yahrzeit* (year's time) candle and attending services where the Kaddish is said (Louchheim, 1997).

Other rituals help to address the impact of the death on the larger social system. In the United States, people typically have a will, which is read to the heirs. This ritual provides for the distribution of resources and assets according to the deceased person's wishes. The reading of the will and distribution of the assets help to realign the social system following a death. Obituaries, which are published in local newspapers, are another custom that notifies the larger community of a death. These statements often acknowledge the person's accomplishments and recognize their family members. This public statement can provide an opportunity for community members to offer support and condolences to the bereaved family members.

A recent innovation is the practice of posting a **tribute** to a loved one on a memorial website (Miller, 2014). A memorial website can be set up so that family and friends can share photos, videos, fond memories, and anecdotes of the deceased. Often the website includes a biography of the person and key life events. People can send condolences to family members, and may be directed to special charities where contributions can be given in memory of the deceased. The following is a tribute posted on a memorial website.

> My grandma was the strongest and most beautiful person that I've ever known. She would light up a room when she walked in and had a wonderful warmth to her that made everyone love her. Although she has been gone from us for nearly 7 years—her spirit remains in each one of us. Life has not been the same without her here but we know that she is in a better place and that she looks over all of us. I've heard from many the famous quote of "it will get easier with time" but when you love someone that much it doesn't ever get easier. I think you just come to accept the outcome. Grandma—We miss you and Love you so much!! Not just today but Everyday!!! Love–your family. (Hospice of Michigan, 2007)

The concept of **legacy** refers to what a person leaves behind after death. People may leave a legacy to their loved ones, such as passing on material possessions, a business, or a family history. They may have a larger societal impact in mind, even an impact on future generations, as when people endow a professorship at a university or a wing of a hospital. Legacies are a way to transmit one's resources, values, and wisdom in order to support and comfort those who survive one's death (Newton & Jones, 2016).

There are also many ways that the living can memorialize the deceased, including making contributions to charities in the name of the dead person, creating monuments, naming buildings or programs, listing names on a wall or plaque, and establishing scholarships, grants, or other types of endowments. It is not uncommon to see a small memorial set up at a place on the road where someone was killed in an auto accident. At the park where we often go to enjoy the ocean, people have dedicated benches to family members who used to come there. Every year, the family and friends of a loved one participate in the "Boston Brain Tumor Ride" to raise money for research about brain cancer in her memory. In these and many other ways, people cherish the memory of their departed family and friends.

Memorializing can be at a personal level, but it can also occur on a larger scale. In the face of widespread catastrophes or deaths during wartime, a monument can be erected that honors the victims and also reminds the public of the meaning and impact of the events surrounding the loss (Pollack, 2003). In the wake of the terrorist attacks of September 11, 2001, public memorial services were televised to permit national and international mourning. A National September 11 Memorial and Museum has been created to keep the individuality of the victims alive, to teach about the historical and social contexts of the attack, and to examine its continuing influence as we strive toward a more peaceful, hopeful future.

The **Human Development and Diversity** box The Amish Way of Death illustrates how one culture openly incorporates

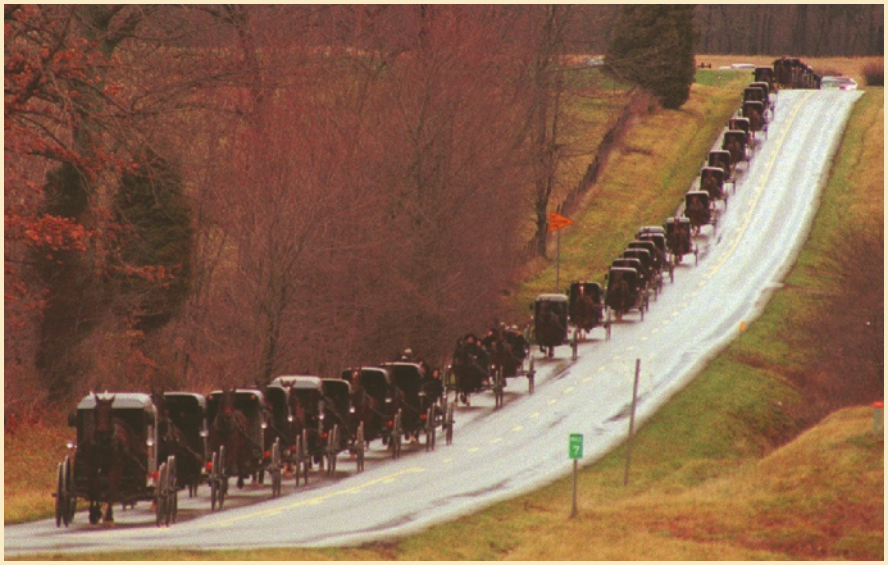
The Amish Way of Death

The importance that the Amish place on their funeral ceremonies is reflected not only in familiarity with death, but also in an intensified awareness of community. As an Amish man reported in a family interview, "The funeral is not for the one who dies, you know; it is for the family."

The Amish community takes care of all aspects of the funeral occasion, with the exception of the embalming procedure, coffin, and horse-drawn wagon. These matters are taken care of by a non-Amish funeral director who provides the type of service that the Amish desire.

The embalmed body is returned to the home within a day of the death. Family members dress the body in white garments in accordance with the biblical injunction found in Revelation 3:5. For a man, this consists of white trousers, a white shirt, and a white vest. For a woman, the usual clothing is a white cape and apron that she wore at both her baptism and marriage. At baptism, a black dress is worn with the white cape and apron; at marriage, a purple or blue dress is worn with the white cape and apron. It is only at her death that an Amish woman wears a white dress with the cape and apron that she put away for the occasion of her death. This is an example of the lifelong preparation for death as sanctioned by Amish society. The wearing of white clothes signifies the high ceremonial emphasis on the death event as the final rite of passage into a new and better life.

Several Amish women stated that making their parents', husbands', or children's funeral garments was a labor of love that represented the last thing they could do for their loved ones. One Amish woman related that each month, her aged grandmother carefully washed, starched, and ironed her own funeral clothing so it would be in readiness for her death. This act appears to have reinforced for herself and her family her lifelong acceptance of death and to have contributed to laying the foundation for effective grief work for herself and her family. This can be seen as an example of the technique of preventive intervention called *anticipatory guidance* (Caplan, 1964) which focuses on helping individuals to cope with impending loss through open discussion and problem solving before the actual death.



AP Images/Peter Wright

At the time of death, the whole Amish community comes together to support the mourners and say farewell to their friend.

After the body is dressed, it is placed in a plain wooden coffin that is made to specifications handed down through the centuries. The coffin is placed in a room that has been emptied of all furnishings, in order to accommodate the several hundred relatives, friends, and neighbors who will begin arriving as soon as the body is prepared for viewing. The coffin is placed in a central position in the house, both for practical considerations of seating and to underscore the importance of the death ceremony.

The funeral service is held in the barn in the warmer months and in the house during the colder seasons. The service is conducted in German and lasts 1½ hours, with the same order of service for every funeral. The guests view the body when they arrive and again when they leave to take their places in the single-file procession of the carriages to the burial place.

Critical Thinking Questions

1. Summarize how the Amish way of death addresses the care of the body, spirit, and surviving loved ones.
2. Analyze the cultural worldview, values, and beliefs about life after death that are reflected in this narrative about death-related rituals among the Amish.
3. What can you find out about the Amish beliefs regarding the afterlife?
4. Interpret the meaning of the various symbols in this narrative, including the white clothing, plain coffin, funeral taking place in the barn, and procession of horse-drawn carriages.
5. Compare the funeral rituals of the Amish with the rituals described for the Hindus and Navajo Indians. What might be some similarities and differences in beliefs that are reflected in these practices?

death into every aspect of life. The service and ritual are expressions of the belief in a spiritual immortality and a simultaneous recognition of separation. Families customarily care for their aging parents in their own homes. Dying persons are surrounded by their families, who provide reassurance of generational continuity (Greksa & Korbin, 2004). In one study, Amish families found six conditions especially helpful for coping with death (Bryer, 1979, p. 260):

1. The continued presence of the family, both during the course of the illness and at the moment of death
2. Open communication about the process of dying and its impact on the family
3. Maintenance of a normal lifestyle by the family during the course of the illness
4. Commitment to as much independence of the dying person as possible
5. The opportunity to plan and organize one's own death
6. Continued support for the bereaved for at least a year following the funeral, with long-term support given to those who do not remarry

FURTHER REFLECTION: *Describe the elements of a funeral you have attended or observed. What are the features of a funeral that address the care of the body, the spirit, and the surviving family and community?*

What are some strategies for memorializing the deceased? Which ones have you found to be especially effective?

Bereavement and Grief

OBJECTIVE 5 Analyze factors that affect grief and bereavement.

Three terms—bereavement, grief, and mourning—are associated with the death or loss of a close relationship. Bereavement refers to the loss of a meaningful relationship; grief is the complex set of emotions and thoughts that accompany this loss; and mourning is the social and behavioral expressions of loss, often guided by cultural practices (Fontana & Keene, 2009).

Bereavement

Bereavement is a long-term process of adjustment to the death of a loved one and is more all-encompassing than grief. It commonly includes physical symptoms; role loss; cognitive manifestations, such as seeking meaning in the loss or trying to solve problems that arise as a result of loss of the loved one; and a variety of intense emotions, including anger, sorrow, anxiety, and depression. Bereavement may be expressed in very individual ways and may also be guided by cultural practices that shape the behaviors and activities of those in mourning. The bereavement process can include both confronting the loss and seeking ways to move away from or beyond the loss. It can include the expression of pain, sorrow, and loneliness as well as the possibility of self-insight, redefinition, and psychosocial growth. The bereavement process can be viewed as a form of coping as the person confronts the loss and its secondary stressors (Hansson & Stroebe, 2007).

Bereavement and Coping with Stress

Some authors conceptualize bereavement within a more general framework of coping with stress. In Reuben Hill's (1958) ABCX model of coping with stress, adaptation (X) is determined by the interaction among three factors: the initial stressor (A), the resources and social support a person has to deal with the stressor (B), and the perception or meaning the person makes of the situation (C). The model was expanded into the double ABCX model (McCubbin & Patterson, 1983) to reflect the changes in the family system over time as the initial stressor is met and subsequent events bring new stressors, alter the existing resources, and change perceptions of the event (FIGURE 15.1 ▶). As this model suggests, efforts to cope with the initial stressor result in changes in the situation that alter the family's adjustment. Initial coping strategies may reduce or improve the family's resources, perceptions of the original stressor may change with time, and new secondary stressors may arise that impact the family system.

The value of this model for understanding bereavement is its emphasis on individual contexts of the death, the dynamic and changing nature of the stressor and its impact over time, and the key role that meaning making plays in how a person will adapt to the loss of a loved one. For example, a death might be perceived as unfair, sudden, cruel, or too soon by some but perceived as a blessing, or timely, by others. Positive or negative appraisal of the loss may influence the emotional state that emerges. If the person gains new insights into the loss and is able to construct positive meaning in the situation, some of the distressing negative emotions may subside and be replaced by positive emotions that could foster subsequent adjustment (Hansson & Stroebe, 2007).

With respect to resources, the loss of a life partner might be followed by the loss of social status, income, and companionship, but this same loss might result in new financial resources such as life insurance, fewer medical bills, and freedom from caregiving responsibilities. Over time, bereavement might have an impact on a survivor's health. The depression and confusion that accompany

grieving may decrease the survivors' sensitivity to their own physical health and pose risks to their mental health as well. People in deep mourning may have feelings of uselessness or emptiness that prevent them from seeking help for their own physical or emotional health problems. Some people try to cope with their grief by increasing their use of medication, alcohol, or tranquilizers, which may threaten their physical health. Loss of appetite and lack of sleep are other symptoms of grief that contribute to the pattern of increased vulnerability during this time. In contrast, others may find a new sense of purpose and commitment to life as a consequence of bereavement. They may take new steps to improve their own health and to treasure their days, realizing that life is precious. In order to understand the adaptive nature of the bereavement process, one must appreciate that the meaning a surviving loved one gives to the death and the resources that are available to cope with the loss are changing over time.

Grief

Grief refers to the cognitive and emotional reactions that follow the death of a loved one. Grief reactions can vary in duration and intensity and can fade and reappear at unexpected moments. In a study of family members who were responsible for caring for a person suffering from later-life dementia, five aspects of grief were identified: (1) preoccupation with thoughts of the deceased person, (2) longing for the person, (3) painful emotions, (4) feelings of dissociation—feeling disconnected from reality, and (5) sensory illusions that led to the impression that the deceased person was still present. Of these five aspects of grief, preoccupation was the most common and lasted the longest after the person's death (Aneshensel et al., 1995).

Sometimes intense grief reactions are very similar to symptoms of mental illness (Hospice of Michigan, 2007). The following symptoms are not unusual:

Time distortion: Time seems to be frozen, the person is unsure what day it is, time moves unusually slowly or speeds by.
Obsessive rumination: Telling a story or incident over and over; thinking about a situation involving the dead person over and over.
Suicidal thoughts: Thoughts that the person cannot go on living without the deceased person in their lives.
Mystical experiences: Experiences of seeing or hearing the person who died, sensing them with you.
Identification symptoms: Experiences of symptoms that are similar to those of the person who died.
Increased use of drugs and alcohol: Used to buffer experiences of pain from the loss.
Confusion: Difficulty concentrating or making decisions.

There is no timetable for grief. One study followed the grief reactions of family members whose loved one died from cancer (Ringdal, Jordhov, Ringdal, & Kaasa, 2001). The intensity of grief response showed significant declines by the end of the first year after the death. In monitoring the grief response, however, one often finds conflicting evidence of devastation and impressive coping. A widow may be handling daily tasks at a high level of competence and still find herself in tears at seeing her husband's hat in the closet. Over time, one expects to see gradual improvement in the intense, disruptive feelings of grief, but it is hard to say if there is a time when mourning is completed. Perhaps the most important sign is that the person is able to reinvest in new activities and relationships, even while preserving affection for the deceased loved one.

Grief Work

In the face of the death of a loved one, there is a need to work through the reality of the loss as well as the feelings that accompany it. The experience of the bereaved person is not that different from the experience of the person who is coping with his or her own death. Psychiatrist Erich Lindemann (1944) worked with people whose relatives died in the Coconut Grove fire in Boston. His writings continue to provide a basis for understanding the bereavement process.

Lindemann described three phases to the normal grief reaction. First, the person must achieve "emancipation from bondage to the deceased." This bondage may include feelings of guilt about ways in which he or she had criticized or even harmed the person who had died, or feelings of regret for things left unsaid or undone. Second, the person must make an adjustment to all the aspects of the environment from which the deceased is missing. The more closely linked the lives of the living and the dead, the more difficult this may be. Third, the person must begin to form new relationships—what we have called redirecting energy to new roles. One major obstacle to working through this loss is a desire to avoid the accompanying emotions and intense physical distress. According to Lindemann's analysis, the strategy of avoiding grief only prolongs the survivor's physical, mental, and emotional preoccupation with the dead person.

Questions have been raised about how universally applicable Lindemann's idea of **grief work** really is. In some cultures, intense emotional expressions of grief are considered inappropriate. Under conditions of grave trauma, some counselors suggest that an early period of denial helps the person cope with immediate demands. For some, the death of a loved one comes after a long period of painful illness. Death may be viewed as a relief from suffering and, as such, brings a form of comfort to those who are still living. Thus, the context of death and its meaning for those who mourn suggests a more individualized view of the adaptive process of bereavement (Hansson & Stroebe, 2007).

Bereavement and Grief Among Older Widows and Widowers

Among people who have lost a spouse, intense depression is more likely to be experienced by those who described their marriage as positive and vital. This loss strikes at the core of an older adult's sense of attachment, social integration, and personal worth (Futterman, Gallagher, Thompson, Lovett, & Gilewski, 1990). In a comparison of older widows and widowers with adults who were not experiencing bereavement, the widowed adults showed greater signs of depression, psychopathology, and grief at 2 months after the loss (Thompson, Gallagher-Thompson, Futterman, Gilewski, &

Peterson, 1991). At 12 and 30 months after the loss, the two groups were comparable in levels of depression and psychopathology, but the bereaved group continued to experience higher levels of grief than the nonbereaved. Among older adults, one may not expect a full resolution of the grief work associated with the death of a spouse. Rather, older adults come to accept a certain empty place in their hearts for their deceased partner and learn to find appropriate times to experience their profound sense of loss.

Five Patterns of Bereavement Among Widows and Widowers

The complexity of bereavement as a coping process is illustrated in a study that followed older couples from before the death of a spouse until 18 months after the death. Five **patterns of bereavement**-related adjustment were identified (Bonanno, Wortman, & Nesse, 2004). These patterns, shown in FIGURE 15.2 ▸, were:

1. *Common grief pattern*. These people had low levels of depression before the spouse died. They experienced an increase in depression 6 months after the loss. After 18 months, they returned to the same low level of depression that characterized them before the loss.
2. *Resilient pattern*. People in this group had low levels of depression before the death of their spouse and continued to have low levels after the death of the spouse.
3. *Chronic grief pattern*. These people had low levels of depression before the loss but showed increased grief responses at both 6 months and 18 months after the loss.
4. *Chronic depression pattern*. These people had high levels of depression before the loss, and depression continued at high levels at both 6 and 18 months.

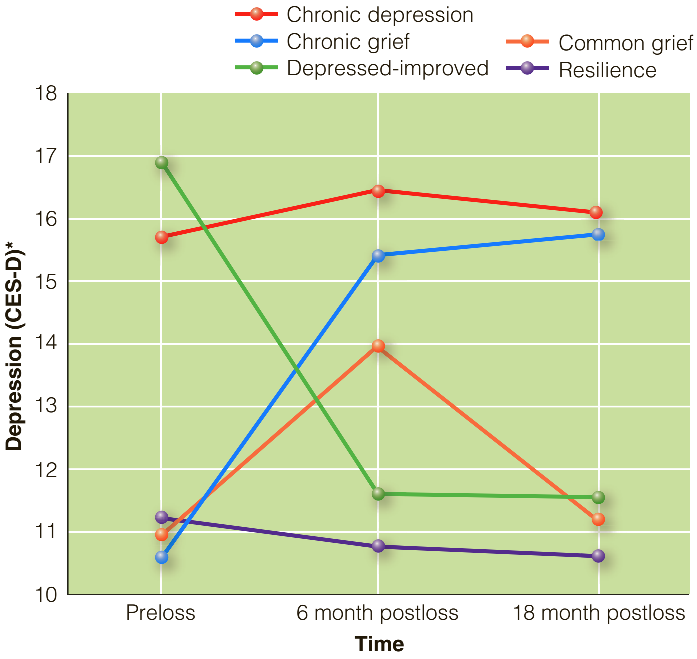

FIGURE 15.2 ▸ FIVE PATTERNS OF BEREAVEMENT

*Note: Depression measured by the Center for Epidemiologic Studies of Depression (CES-D). Bonanno, Wortman, & Nesse, 2004, Fig. 1, p. 263. Copyright © 2004 by the American Psychological Association. Reprinted with permission.

5. *Depressed-improved pattern*. These people had elevated levels of depression before the loss, but lower depression scores at 6 and 18 months after the loss.

This research helps clarify the importance of the context of loss as it affects the bereavement process. The context of the loss can include the nature of the relationship between the deceased person and the survivor, the sudden or gradual trajectory of death, the causes of death, the psychological health of the surviving spouse before the death of the partner, and the extent to which a spouse believes that the deceased had led a full life. The depressed-improved group, for example, was composed of people who were in unhappy or unsatisfying marriages; many had a substantial caregiving burden for an ailing spouse. Although people in this group did show evidence of grief responses at 6 months, they also reported benefits of widowhood and pride in the ability to cope with their new status.

In contrast, the chronic grievers comprised people whose lives were suddenly disrupted by the death of a healthy spouse. This group was especially preoccupied with a search for meaning as they tried to make sense of their spouse's death. They had sustained experiences of yearning for their spouse, thinking about their spouse, and talking with others about their spouse at 6 months, with some evidence of improvement in these aspects of grief by 18 months. The results of the study suggest that for some groups, especially the resilient and depressed-improved groups, the

Bernice comes each month to visit with her husband at the cemetery. She never remarried and still thinks of herself as Bill's wife. She finds comfort knowing that her husband died bravely in the service of his country.

relative lack of expression of grief-related symptoms may not be due to denial of their loss, but to evidence of appropriate coping.

Complicated Grief

The pattern of chronic grievers described above can be considered an example of **complicated grief**. Where the typical symptoms of grief gradually fade with time, in complicated grief the person remains in a continuing state of deep mourning for 6 months or more. In some instances, the grief reactions become more intense over time. Some signs of complicated grief include the following: intense sorrow and pain when thinking about the loved one, intense longing for the loved one, problems accepting the death, an inability to focus on anything other than the loss, a feeling of numbness or detachment, and a loss of ability to think about periods of enjoyment in the past or to experience enjoyment in the present. The combination of these symptoms may create anxiety, depression, an inability to sleep, increased risk of illness, and difficulty engaging in basic tasks of work or family life. Dr. M. K. Shear reported on the following case:

> A 68-year-old widow who continued to be seriously impaired by grief four years after her husband died. The woman slept on the couch because she could not bear to sleep in the bed she had shared with him. She found it too painful to engage in activities they used to do together. She no longer ate regular meals because preparing them was a too-distressing reminder of her loss. And she remained alternately angry with the medical staff who cared for him and with herself for not recognizing his illness earlier. (Brody, 2015; Shear, 2015)

The causes of complicated grief are not entirely understood. They may be related to the context of the loss, a lack of an adequate support system, a vulnerability to depression, or some co-occurring stressors that overwhelm the person's typical coping capacities (Mayo Clinic, 2014d).

Factors That Affect the Distress of Survivors

As illustrated in the study of patterns of bereavement among widows, the bereavement path depends in part on the context of the loss. Grief may be more intense for those who lose a loved one in a sudden death. Under these conditions, there is no opportunity to discuss end-of-life decisions, for final expressions of caring and love, and for the bereaved to begin to anticipate life without the loved one (Howarth, 2007). In cases of natural disaster, the death of loved ones may be accompanied by loss of home, neighbors, and a sense of place.

Bereavement may be difficult if the dying person is unable to receive effective pain control in their last days of life. Survivors who feel that the death of their loved one was brought about by physicians' negligence feel greater distress and anger than survivors who feel that the loved one received high-quality medical care. An aspect of the dying process that is seen as negative for the dying person but is protective for the survivor is nursing home usage. It leads to reduced anxiety for the survivor and may prepare them for the separation that death finalizes while sparing them from the burden and strain of direct caregiving.

HECTOR RETAMAL/AFP/Getty Images

In October, 2016, Hurricane Matthew brought devastating destruction and loss of life to families in Haiti. The combination of sudden loss and disruption of family life can result in complicated grief.

Ambiguous loss is another especially difficult challenge for loved ones. Two types of ambiguous loss have been described (Boss, 1999). In the first instance, the person is missing and may be dead, as in soldiers who are missing in action or people who may have died in a disaster, but there are no physical remains. In the second instance, the person is physically present but unable to participate in any meaningful way in family interactions, as when a person is in a coma or in the late stages of Alzheimer's disease. As a result of the destruction of the World Trade Center in New York, some children experienced both types of losses: One parent died in the destruction of the towers, but no remains were recovered, and the other parent was so distraught by the spouse's death that he or she became unable to enact the parent role (Boss, 2004). The **Applying Theory and Research to Life** box Ambiguous Loss describes some of the issues surrounding this unique context of bereavement.

Finally, bereavement may be especially difficult if the survivor has experienced many positive benefits of caregiving, including feelings of being needed, important, and effective, as they addressed the needs of an ailing spouse (Boerner, Schulz, & Horowitz, 2004). Although family caregiving is often viewed as a source of stress, some people find that they gain comfort and even a personal sense of worth through caregiving. In this context, the death of the ailing spouse or parent brings a double loss—loss of the loved one and loss of the meaningful caregiving role.

Unacknowledged and Stigmatized Loss

The bereavement process is influenced by a society's interpretation of who the legitimate mourners are and who has experienced a legitimate death. Some people who grieve may not be recognized as legitimate mourners. These might include former spouses, foster children, partners in a gay relationship, professional caregivers, extramarital lovers, families of addicts and criminals, or women who have had abortions. When communities do not

APPLYING THEORY AND RESEARCH TO LIFE

Ambiguous Loss

Of the 2,749 people who were reported missing after the attack on the World Trade Center in New York on Sept. 11, 2001, 1,640 have now been positively identified (Dunlop, 2015). Despite the use of a variety of approaches to identification, more than 9,000 body fragments were not identified. These fragments were stored for future analysis, in case new technologies are developed that allow for their identification. At some point after the tragedy, the mayor of New York offered presumed-death certificates to families when there was no body that could be identified. Some families accepted those certificates, whereas others continued to wait for DNA testing results. In ensuing years, through the process of cleaning up debris from roads and nearby buildings, and the excavation of the Ground Zero site, some additional human remains were discovered (9-11 Research, 2013). Thousands of families suffered ambiguous loss—some for days not knowing if their loved one was in the buildings, many for months as they waited for the remains to be excavated from Ground Zero, and some are still suffering because there is no physical evidence of their loved one's body.

Pauline Boss (2002b, 2004, 2007) developed an understanding of ambiguous loss through clinical observation, theory, and research. She worked with many families who have experienced this type of loss, including merchant marine families, soldiers' families, families whose loved ones died in the terrorist attacks of September 11, 2001, and families in Kosovo. Much of this discussion is based on her observation and methods.

Ambiguous loss poses significant challenges to the structural and functional characteristics of a family. Families may try to hold a place for the person in daily life. Confusion about whether a loved one is dead or alive may lead some families to ignore parental roles, put off decisions, neglect daily tasks, and isolate living family members. Many families stop carrying out rituals and celebrations, which leads to further disconnection among family members.

Psychologically, the chronic uncertainty and lack of new information produce feelings of hopelessness, passivity, and immobilization. Because they do not have proof of death, family members may become confused—they do not know what to think or how to act. They may become stagnant by denying the loss and continuing to hope. The result is that family members are not grieving, and they are not coping with their loss.

Questions arise such as, "Should you have a funeral if you do not have a body?" Families would get into protracted arguments about this. Some parents did not want to tell their children that their father or mother was dead. Many children got the impression that they were not supposed to talk about the missing parent. People in these families are trying to hold two opposing ideas in their minds: (1) the loved one is still alive, and (2) the loved one is dead. As a result, their grief process is blocked. It takes a very long time to create a family life that includes acceptance and integration of this ambiguity.

Boss used several techniques that helped people cope with their loss. First, she created family storytelling meetings, where adults and children were encouraged to tell something they remembered about the missing person. Second, she arranged for groups of families who lived in the same community to meet together and tell stories about their missing family members. These meetings helped foster community connections. People were able to identify others who had the same needs, and they began to find ways to meet those needs. Third, she explained the idea of ambiguous loss and helped people see why it was causing them so much distress. This helped reduce self-blame and family discord. Fourth, she encouraged families to revise family rituals and celebrations but to continue having them because they are so important to preserving the unity of a family. Fifth, she told them not to become agitated and distressed by pushing for closure. She believes that closure is a myth and that death always produces ambiguity and uncertainty. Being done with grief, putting an end to mourning, and moving on are unrealistic expectations. Some families were less distressed than others. The characteristics of these families included a belief that the loss of the loved one was predestined and perhaps a product of the will of God; some had a deep faith that God would care for their loved one and guide them; some had prior experience in coping with ambiguous loss; and some were cognitively or temperamentally better able to hold the two opposing ideas in their minds and still retain the ability to function. Boss (2004) reported some comments that were made to her by people who were less distressed: "My son has been missing so long now—he's probably dead, but I feel he's here with me, and always will be" (p. 559). "I must move on and organize life without my son, but at the same time I can hope and remember" (p. 559).

Critical Thinking Questions

1. Summarize the challenges of ambiguous loss that interfere with the bereavement process.
2. Critically evaluate the five techniques Boss has developed to help people cope with their loss. What might be helpful about these strategies? Why might these techniques be helpful? Are there aspects of these strategies that might not be helpful? Why not?
3. Classify people into those who might be more or less troubled by ambiguous loss. Why? Which types of people would be most likely to benefit from Boss's approach? Why?
4. Propose other kinds of interventions, aside from those mentioned here, that might be helpful in supporting survivors of ambiguous loss.
5. Compare differences in the challenges of coping with ambiguous loss and stigmatized loss.

sanction or support their grief, it may be difficult for these people to acknowledge that they have suffered a loss or to experience closure after the death. These **unacknowledged mourners** may be confused about their status and feel guilty or embarrassed by their attachment to the dead person (Murray, Toth, Larsen, & Moulton, 2010).

There are also situations in which a person survives a loved one who had a stigmatized death. **Stigmatized deaths** are those in which people attribute the death to an immoral, illegal, or evil cause. Some survivors feel conflict in their grief and anger toward the dead person because they believe that person was involved in immoral or unclean behavior. These feelings may lead the griever to secrecy and misrepresentations about the death. Social networks may shun people who are grieving for someone who died a stigmatized death. Negative stereotypes surround these deaths and are often extended to include survivors (Murray, Toth, Larsen, & Moulton, 2010).

Death by suicide is an example of a stigmatized death, in which survivors may feel guilty about not having been able to prevent the death and angry at that person for the suicide. They may experience great conflict because of their love for the person who died and their belief that death by suicide is immoral. Communities look down on death by suicide and may not provide the customary rituals that help support the grieving persons. Many religions consider suicide to be a sin and will not provide religious services or burial rights for the deceased. In a qualitative study of adults who were mourning people who had committed suicide, two persistent themes were trying to make sense of the death and struggling to manage the social uneasiness in interactions with others. Meaning making was a key factor in the coping process for these survivors, including the meaning of the suicide, the meaning of the relationship between the survivor and the person who committed suicide, and the meaning of the survivor's own life (Begley & Quayle, 2007).

Death as a result of AIDS is another example of a stigmatized loss. In the 1980s, as the AIDS epidemic was taking hold, many survivors found that there was little support for their grief. The devastating effects of AIDS and the associated end-of-life conditions, compounded by fear of contamination, left many survivors isolated and traumatized by their stigmatized loss. In 1985, gay rights activist Cleve Jones discovered that more than 1,000 people had died of AIDS in San Francisco alone. He and other activists conceived of the NAMES Project AIDS Memorial Quilt as a way of honoring and memorializing this loss. The first national display of the AIDS Quilt took place on the National Mall in Washington, DC, at a lesbian and gay rights march in 1987. At the time, the quilt had 1,920 panels and was seen by more than half a million people. By 1988, the quilt was taken on a 20-city tour and had grown to 6,000 panels. In 2005, the quilt was named an American Treasure, resulting in a grant to support the conservation of the quilt. Today, there are 10 NAMES chapters in the United States and 29 affiliates around the world. The quilt has 46,000 panels commemorating the memory of over 96,000 people who have died from AIDS (The NAMES Project Foundation, 2016). As a result of this and other initiatives, the focus shifted from shunning the ill to investing in new medical research for causes and cures. Resources were invested in research about AIDS, AIDS education, and the discovery of treatments to slow the course of the illness and prolong life.

CORBIS/AGE Fotostock

The AIDS Memorial Quilt displayed on the Mall in Washington DC.

In the United States and throughout the world, the death of adult children as a result of AIDS is resulting in the increased involvement of grandparents who are parenting their orphaned grandchildren (Linsk & Mason, 2004; Winston, 2006). In a qualitative study of South Africans who had lost a loved one to AIDS, bereaved adults described their situation as so overwhelming that there was little time for the typical experiences of grief (Demmer, 2007). The struggle for daily survival was intensified as a result of the economic losses associated with the death of an adult member of the household. Older women were burdened with the tasks of caring for the sick and looking after the surviving children. In this context, customary practices associated with mourning and loss were set aside in order to continue to meet the pressing demands of daily life.

Comforting the Bereaved

You can appreciate that there is no single way of experiencing loss, no right or best way to mourn, no specific timetable for recovering from the strong feelings of loss, and therefore, no one best way to comfort a bereaved person. The person in mourning is probably experiencing a range of emotions that fluctuate from moment to moment, and in the intensity of their grief they may also feel isolated and exhausted. The more you understand about grief and bereavement, the better able you are to provide comfort and support. And the way of approaching the role of providing comfort depends on the context of the loss, the meaning the loss has for the person, and the nature of the relationship between a bereaved person and one trying to offer comfort. Nonetheless, the literature on bereavement consistently mentions the importance of having a supportive social network as one factor that helps people cope with their loss. The role of the supportive network may be clearly defined by religion or culture, or it may have to be "improvised" by those close to the person who is mourning. The following suggestions are offered by therapists and grief counselors (Smith & Segal, 2016):

Listen with compassion. Acknowledge the situation, and let the person know you care and are there to listen or to help. Without forcing a person to talk about their loss, be ready to listen openly without judgement. You may ask, "Do you feel like talking?" Be patient if the person needs to tell their story over and over. Share your experience if you feel it's appropriate, but don't tell the person you know how they feel since each person experiences their loss in a very personal way.

Check in often and continuously. Friends who continue to call, stop in, or send emails or text messages in the initial few weeks after the death are especially valued. Often, the person can't even respond, but this doesn't mean they are unaware or unappreciative of this continuing support. "From pure exhaustion I often chose not to respond, but I felt incredibly supported by these messages and much less alone" (Tempesta, 2015).

Take the initiative in offering simple acts of help or service. The general statement, "What can I do to help?" is often impossible for the bereaved person to answer. They may feel so overwhelmed or confused that they can't even figure out what they need. But specific suggestions like bringing over a meal, offering to go grocery shopping, coming over to help fold the laundry, suggesting to go for a walk together, or picking the kids up after school might be really appreciated. Since the process of bereavement may continue for months, continuing to make these efforts is highly valued. Special efforts may be particularly important at certain times, like holidays, birthdays or anniversaries, and the anniversary of the death.

Watch for signs of complicated grief or the emergence of serious depression. After 4 to 6 months, you ought to notice some easing of the signs of grief. If you begin to realize that the person is unable to function in daily tasks, neglecting personal hygiene, unable to sleep, withdrawing from others, or expressing continued feelings of helplessness or hopelessness, you might share your concern with them, "I am troubled that you aren't sleeping and you seem to have given up on many of the things you used to enjoy." Any mention of suicide or increasing use of alcohol or drugs are to be taken seriously as signs that professional intervention is needed (Smith & Segal, 2016).

FURTHER REFLECTION: *Summarize the various contexts that can impact the nature and severity of the bereavement process. How might the reason for a person's death, the age of the person, or the role of the person in one's life impact bereavement? How might stigmatized loss impact the bereavement process?*

Psychosocial Growth Through Bereavement

Bereavement brings new possibilities for psychosocial growth. Just as happiness and joy are innate human emotions, so is sadness. Having these feelings is part of the human experience. Even though they are unpleasant, the emotions associated with grief connect people to their essential human nature. Expressions of grief have a social consequence. An infant's cries have the effect of bringing the caregiver into contact with the infant; the tears of grief communicate to others a person's needs for comfort and reassurance. Without experiences of grief, the moments of treasured happiness would mean less. These experiences help people understand the essence and limits of their existence. They provide a bridge for understanding the grief and unhappiness of others. Grief leads to greater levels of understanding of oneself and others.

The adaptive process of bereavement involves an oscillation between **loss-oriented coping** and **restoration-oriented coping**. The former refers to confronting one's pain, sadness, and the loss of a loved one and finding a place for the deceased loved one in one's thoughts and memories in order to achieve emotional health and cognitive functioning. The latter refers to finding ways to master the practical challenges of the loss in order to make meaning of the death and move along in one's life (Caserta & Lund, 2007; Hansson & Stroebe, 2007). When a person who is close dies, it stimulates reflection about that relationship. There may be a new appreciation of the qualities of the relationship and its importance. One may consider what the other person did to make the relationship especially valued. The bereaved person may begin to examine his or her own behavior, thinking of ways to bring some of the valued qualities of the relationship with the dead person to ongoing friendships and family ties. People may make resolutions to do a better job of supporting valued relationships by staying in touch, writing more often, or calling home. In the process of experiencing the death of a loved one, a person may become more appreciative of the value of these special, close relationships, realizing that they will not last forever. It is important to give valued relationships appropriate care and nurturance. This may lead to a growth in commitment to one's radius of significant relationships and to maintaining excellent quality in them.

The death of a loved one may stimulate a process of life review, leading one to reflect on the meaning of one's life. This process of taking stock may involve posing some of the big questions of life: What is the purpose of your life? Are you spending time in ways that are meaningful? Is your work an expression of your real values? Are your relationships satisfying and meaningful? Are you making any contribution to your community and to the well-being of others? This kind of reflection may lead to a reformulation of one's lifestyle or a re-evaluation of certain life experiences.

The death of someone whose presence serves to help define your identity requires a redefinition of your identity. Social roles are typically reciprocal—children have parents, husbands have wives. The death of someone in a reciprocal role leads to the reorganization of that role and its enactment. When a parent dies, children may have to assume some elements of the parental role. These elements are often concerned with greater levels of responsibility and caregiving. When a spouse dies, the remaining spouse has a new identity as a widow or widower. This brings with it new social meaning and, sometimes, a change in social status.

When a person dies, the links to social identity and social network may no longer exist for the person who remains. As a result, the survivors have to redefine themselves and establish new personal identities. For example, when Carl died, his wife Lois was no longer invited to social events that were hosted by Carl's coworkers. Lois no longer maintained her membership at Carl's golf club. She found that it was awkward to introduce herself to new people without being able to say that she was Carl's wife. She recognized that her social status was based on Carl's work and leisure activities. Being Carl's widow did not carry the high level of social status and value that she was used to. Lois had to begin to create a new identity in her community. This work is not easy, but it is very important and necessary.

The death of a loved one may stimulate a revisitation of psychosocial crises. For example, upon the death of a parent, one may reflect on earlier issues of autonomy versus shame and doubt, realizing a new sense of responsibility for one's actions. When parents are alive, even as they get older, an adult child is somehow buffered from the full weight of autonomous self-determination. When parents die, one may reflect on the many ways in which their values and beliefs have guided one's attitudes and behavior.

When a spouse dies, in addition to the need to reconfigure one's identity, issues of intimacy versus isolation may be revisited. A person may reflect on the quality of his or her intimate relationship, thinking about the nature of trust, levels of disclosure, sense of mutual respect, and openness to change. One may reexamine the ways in which intimacy was expressed and the ways in which isolation was experienced in the relationship. If the opportunity arises for the formation of a new intimate relationship, this revisitation could lead the person to approach that new relationship with different strategies, assumptions, or expectations for self and other.

When a person you admire dies, it often promotes new levels of identification with the deceased. This process sometimes begins with the eulogy where the community is reminded of the strengths and accomplishments of the person who died. In reflecting on the person's life, a survivor may take on a valued characteristic, such as integrity, fairness, sense of humor, or patience. Survivors may find themselves using expressions or participating in activities that were associated with the person who died. In this way, they expand their repertoire of behaviors, activities, and ego strengths. In addition to identification, the survivor may *introject* the lost person (i.e., take the person's essence inside themselves in thought and feelings). **Introjection** is different from identification in that the person feels that the lost person is in them. They may carry on meaningful conversations with this person and sense their guiding presence. This is similar to having an imaginary companion. Introjection allows the bereaved person to keep the dead person alive and to preserve their relationship. While still carrying on a mature and sensible existence, the bereaved add a psychological dimension to their abilities by preserving the characteristics of the revered and adored loved one.

In bereavement, thoughts are likely to turn to one's own mortality. The manner of the loved one's death and the way he or she faced death may help survivors prepare for their own death. The dead person's courage may lead the living person to work to develop courage. The creation of a living will by the deceased may be seen as beneficial by the surviving people, who proceed to establish their own living wills. The depth of emotion created by the death of someone close helps individuals recognize the value of their own lives and the emotions that significant others will experience when they die. In bereavement, a person can find comfort in the faith, confidence, and hopefulness of the person who died and be inspired to achieve that sense of integrity with regard to his or her own death.

FURTHER REFLECTION: *Create a memorial ritual that would help support continued psychosocial growth for bereaved loved ones.*

CHAPTER SUMMARY

The field of human development has come to a new openness about the topics of death and dying. There is an increasing sense that people can make decisions about the quality of their death and that these decisions can and should be discussed with family members as well as with health care professionals. In addition to experiences with death and the anticipation of one's own mortality, dialogues about death are taking place in families to a greater degree than they did in the past.

OBJECTIVE 1 Explain how mortality influences psychosocial development

The psychosocial perspective helps direct attention to how people determine the meaning of the events of their lives as they interact with the environment over time. Death presents one of the greatest challenges to meaning making. At each stage of life, our understanding of death changes because of the different cognitive and emotional resources we have available and as a result of the salience and proximity to death. The way people conceptualize their own death and the death of others is influenced by the cultural context.

OBJECTIVE 2 Define the biological state of death, including the distinctions between cardiopulmonary and whole-brain death.

The definition of the biological state of death has changed as a result of the development of new technologies. In addition to the lack of a heartbeat and the lack of respiration, death is determined by a combination of eight criteria that confirm the end of brain functioning. New legal procedures or advance directives allow people to convey their preferences about end-of-life treatment and to appoint people to make decisions for them if they are incapacitated.

OBJECTIVE 3 Describe factors associated with the process of dying and the modern ideal of a good death.

The process of dying can follow different trajectories, involve different degrees of suffering, and occur at different ages. Professionals have begun to define characteristics of a good death, and dying patients are having a greater voice in determining the nature of their death. Hospice care and euthanasia are two paths that people may choose when they are experiencing a slow, painful death trajectory. End-of-life decisions are a focus of ongoing ethical controversies and debate.

OBJECTIVE 4 Summarize the role of cultural death-related rituals and their functions.

Death-related rituals are found in all cultures. They tend to focus on three aspects of the meaning of death: (1) care of the body, (2) care of the spirit, and (3) care of the surviving family, friends, and community. These rituals provide a context for acknowledging the death, preparing the spirit for its transition, and legitimizing the grief of the bereaved survivors and providing support for their recovery from the loss over time.

OBJECTIVE 5 Analyze factors that affect grief and bereavement.

Bereavement is the long-term process of adjustment to the death of a loved one. Grief is the cognitive and emotional reaction to loss. The concept of grief work refers to the emotional expression, cognitive reorganization, and social adjustments that take place as a result of the death of a loved one. There are many patterns of bereavement depending on the context of the death, relationship of the survivor to the dead person, religious orientation of the survivor, and finality or ambiguity surrounding the death. Communities play a role in supporting the bereavement process by the way they respect or stigmatize the death and the way they memorialize and honor the dead.

CASEBOOK

For additional case material related to this chapter, see the case "Till Death Do Us Part," in *Life Span Development: A Case Book*, by Barbara and Philip Newman, Laura Landry-Meyer, and Brenda J. Lohman, pp. 195–199. This case focuses on the role of a sudden illness in opening up communication about end-of-life issues for an older couple.

Appendix

THE RESEARCH PROCESS

This appendix highlights basic principles of the scientific process, including the positivist and qualitative approaches to inquiry. This process guides inquiry, and imposes constraints of logic, methodology, and ethics in hopes of building a sound, unbiased understanding of patterns and processes of development. The Appendix reviews basic topics in research design including sampling, research methods, and designs for studying development. A section on evaluating research highlights the need to approach the results of research as a critical and informed consumer, recognizing some of the limitations and biases that may be imbedded in the research process. Finally we review ethical guidelines for conducting research with human participants.

In approaching the challenges of conducting and interpreting research about development, it is useful to think of the following wisdom: Each individual is, in some ways, like every other human being; in some ways like certain groups of human beings more than others; and in some ways like no one else (Kluckhohn, 1961). This wisdom helps explain why the study of development requires a variety of methods including cross-national and cross-cultural comparisons, large sample surveys that rely on statistical analysis for their interpretation, and qualitative studies that give voice to individuals who share their unique life experiences. Studies that summarize the responses or behaviors of groups of people will not necessarily account for the experiences of specific individuals. Similarly, the experiences of individuals will not necessarily be generalizable to larger groups. The study of life-span development is a quest for patterns of continuity and change over time and across historical eras. Some patterns that might characterize the experiences of one cohort may not apply across historical periods.

The Scientific Process

The **scientific process** consists of techniques for acquiring new knowledge, investigating questions of interest, and modifying or correcting previous knowledge. By adhering to a scientific process, researchers are better able to overcome the tendency to want to confirm what they already believe and to discard or ignore evidence that disconfirms their views. As human beings who are studying human behavior, the likelihood of making this kind error is especially great (Lilienfeld, 2012). Two major positions have been taken on how to approach the discovery of knowledge: *positivism* and *qualitative inquiry*, sometimes referred to as *post-positivism* or phenomenology (Bordens & Abbott, 2013).

Positivism seeks causal relationships with the goal of trying to predict outcomes. This approach typically applies statistical analyses to data gathered from many participants in order to test specific hypotheses. In the positivist approach, research hypotheses guide decisions about the nature and size of the sample needed, the site(s) where data are collected, the methods of data collection, and the statistical procedures used to analyze the data.

Qualitative inquiry strives to understand the meanings, motives, and beliefs that underlie a person's experiences. This approach emphasizes the individual's point of view and the subjective understandings that help account for a person's actions. Often this approach begins with examination of a *personal experience*, such as a parent's experience of caring for a child who has a developmental disability; a *process*, such as staff–parent communication in a neonatal unit; or a *unique phenomenon*, such as a near-death experience. Approaches to data collection may change as the study evolves, depending on the nature of the participants, the ideas that emerge, and the researcher's reactions and **interpretations**. Both positivism and qualitative inquiry contribute to a new level of understanding of human behavior.

The Positivist Approach to Research

The positivist research approach is described in FIGURE A.1.▶ The research process usually begins with a puzzling idea or observation. Something needs to be explained or clarified that is currently not explained, or current explanations are inadequate or incorrect. In this process of searching for explanations, one develops a set of interrelated ideas to account for the observation. These ideas—referred to as assumptions, hypotheses, or predictions—constitute a **theory**. The theory is not an end in itself, but a way to begin.

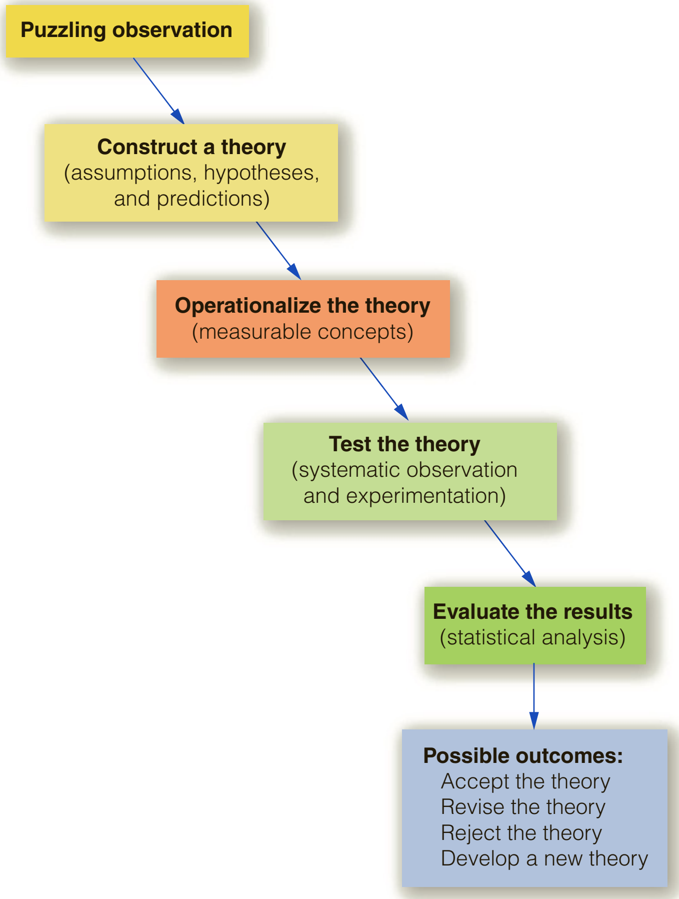

FIGURE A.1 ▶ THE SCIENTIFIC PROCESS

Scientific Observation

The next step of the scientific process is to test the theory through **systematic observation**. A good theory contains specific predictions about cause and effect. After the predictions are stated, one must figure out how to test whether they are accurate. One must **operationalize** the concepts of a theory in order to test them by translating these concepts into variables that can be observed and measured.

Scientific observation is characterized by three essential qualities: It must be *objective, repeatable, and systematic* (Creswell, 2013a). **Objective observations** accurately reflect the events that are taking place. They are not unduly influenced by what the observer expects or hopes to see. Suppose, for example, that you want an objective assessment of your child's talent for playing the guitar. You are unlikely to get objective feedback from friends or relatives. Because they know you and presumably would not like to insult you, they may be inclined to slant their answers to please you.

A more objective approach might be to include an audiotape of your child's guitar playing with tapes of 10 other children. You would then ask another person to play the tapes for 10 people who do not know you or your child and ask each of them to rate the quality of musical ability demonstrated on each tape. You may or may not like the outcome, but at least your method would be more objective. It would reveal what other people think of your child's musical ability without being biased by any feelings. Scientific research is always vulnerable to the theoretical biases and value orientations of the researchers. Certain practices of research design, sampling, and methodology are used to help overcome biases and enhance objectivity. However, many will argue that it is impossible to be entirely objective. One's orientation toward framing research questions and interpreting the results are always influenced by cultural and historical contexts that shape the values, beliefs, and assumptions that guide the research process. That is why it is important that the research be replicated by other investigators and that the procedures are explained in enough detail to be repeatable.

In order for research to be **repeatable**, the original investigator must carefully explain all the procedures used in the study, describe all the essential characteristics of the participants (e.g., age, sex, social class), and describe the setting or situation where the observations were made. When you read a research report in a scholarly journal, these are the details that are included in the Methods section. Because there are many ways that one group of participants might differ from another and many different ways that observations can be made, replication is an important part of building a body of social science knowledge.

A **systematic approach** ensures that research is done in a careful, orderly way. Researchers have a framework of essential questions that they strive to answer based on what is already known and what certain theories predict. They approach research by having clear objectives, carefully defining the purpose of the research, and the specific methods they will use to reach those objectives. Although some discoveries are made by accident, scientific research typically does not poke here and there at unrelated events.

Often the theory is not tested by the same person who develops it because this person may have some personal investment in demonstrating that the theory is correct. The scientific process usually involves the ideas of more than one person. Sometimes, people with different points of view engage in debate, trying to refute positions they find flawed. At other times, two or more people work on different phases of theory building, experimentation, and **evaluation**.

If a theory is fruitful, many researchers working in independent groups devise ways of testing and clarifying it. Working in this way, as a community of scholars, helps to ensure that a theory will not be confirmed simply because of the theorist's personal biases. For example, Erik Erikson was not the person who tested his own psychosocial theory. Many other researchers have devised strategies for operationalizing Erikson's concepts, thereby expanding our understanding of concepts such as hope, identity, intimacy, generativity, and wisdom—to name a few—and clarifying the relationship of development in childhood and adolescence to adulthood and later life.

Statistical techniques help determine the likelihood that observations could have happened by chance. Observations that appear to be a result of chance do not confirm the theory. If the observations have a low probability of having occurred by chance, one says that they are statistically significant. If statistically significant results support the theory's predictions, one is likely to accept them as providing evidence for the theory. However, given the variability of samples, methods, and statistical techniques, no single study can be considered as sufficient evidence to establish a scientific fact (Tryon, 2016).

If the results do not fit the theory's predictions one must reexamine the methods and design of the study. Perhaps the key concepts were not measured appropriately or the sample was limited in some way. When results of research are inconclusive or contrary to the predictions, scholars may try another research approach before revising the theory. But when several different studies fail to support the hypotheses, we tend to lose confidence in the theory. We may revise or discard the theory and begin to develop an alternative explanation for the observations.

In summary, in the positivist approach, the scientific process consists of creating a theory, testing it through research, and modifying, rejecting, or accepting it.

The Qualitative Inquiry Approach to Research

Whereas the positivist perspective assumes that there is a truth that can be captured through the research process, qualitative inquiry assumes that there are many versions of truth, depending on the informant and the context. Knowledge is not out there to be discovered; rather, it is invented, constructed, and continuously revised as one accumulates new information (Creswell, 2013b). The qualitative approach focuses on processes of meaning making. It strives to uncover the ways that individuals understand and cope with the complicated experiences of their lives. In particular, it focuses on the value of "interpretation," recognizing that the same set of events can have different meaning depending on a person's social identity, personal history, and life stage (Karp & Birk, 2013).

The qualitative approach begins with an open mind. One looks at the world as if it were ripe for discovery. Theory typically emerges from the data, rather than starting with a theory that guides the methodology and data collection. When evidence is gathered that contradicts the theory, the theory is rejected or modified. Multiple methods are employed in order to learn as much as possible about the setting, the participants, and the contexts of behavior. In some instances, the observer's own experiences and beliefs are included as a guide to the meaningfulness of the observation. In other instances, the observer attempts to challenge a personal point of view by gathering as many different perspectives about the process as possible. Because qualitative inquiry assumes that there is not one truth, all perspectives and insights are considered equally valid. A major emphasis is on interpretation, made possible by the close acquaintance of the researcher with the details and voices of the participants.

In the study of human development, both positivist and qualitative inquiry are applied, often as complementary approaches to the same issue. Generalizations and categories used in the positivist approach can be reframed or refined using data from qualitative inquiry. Assumptions from the positivist perspective may be challenged by observations made through qualitative inquiry. For example, many children who live in female-headed, single-parent families actually have fathers, uncles, and grandfathers who participate actively in their daily lives. Conversely, many children who live in two-parent families actually have little daily contact with their fathers. Categories and definitions that are assumed to be meaningful from a positivist perspective are often shown to be more ambiguous or diversely defined when considered through the qualitative lens.

Research Design

Regardless of whether the positivist or qualitative approach is used, each empirical study needs to be designed. Research investigations are designed just as cars, bridges, and buildings are designed. Scientists know that the information they gain from conducting research will be influenced by the characteristics of the participants who are involved in their study, the kinds of data that are gathered, and the conditions under which the data are gathered. The principles of **research design** focus on the approach to selecting a sample, the methods used to gather information, the design for studying change, and the techniques used to analyze the data (Gliner, Morgan, & Leech, 2009).

Sampling

Sampling is the method for choosing participants who will be included in the study. The nature of the research questions has implications for the best way to identify the sample. If the study is about some universal principle of development, it should apply to individuals from a wide variety of family and social backgrounds. For example, studies of normal language development should include children from various ethnic, racial, social class, and cultural backgrounds. One cannot argue for universal principles if the research has shown the processes or patterns to be true only for a homogeneous group of children.

Every *sample* is taken from a population. The **population** is the large group to which the findings of the research are intended to apply. There is no single, predetermined population; the relevant population depends on the purpose and scope of the research. The sample is a smaller subgroup of the larger population that will participate in the study. For example, the population of interest might be adolescents in the United States who graduate from high school but do not go on to college. Roughly 906,000 adolescents who graduated from high school in the spring of 2014 were not enrolled in any postsecondary school in the fall of 2014 (National Center for Educational Statistics, 2015e). No study is likely to include all of those adolescents, so a sample is drawn that is expected to be representative of the population. Under ideal conditions, the participants in any study of this population ought to have the same general characteristics (e.g., family income; race; gender; urban, suburban, or rural environment; disability status; and high school academic background) as the population from which the sample was selected.

The sample and the population from which the sample is taken determine the **generalizability** of the research findings—the extent to which we can say with confidence that the observations made for this sample would apply to other groups. We must be careful not to assume that research findings based on one sample are generalizable for all ages, both sexes, all racial and ethnic groups, all social classes, or individuals from other cultures.

Five approaches to sampling, described in more detail in the following sections, are common in the research literature: *random samples, stratified samples, matched groups, volunteer samples,* and *qualitative sampling*. Each one has different implications for the generalizability of the findings (Henry, 2009).

Random Samples

In a **random sample**, each person in a given population has an equal chance of being included. The researcher may ensure equal opportunity by putting each person's name on a slip of paper and then choosing some of the slips blindly, or by selecting names from a list at random, using numbers produced by a random number generator. The Kaiser Family Foundation study of media use by infants, toddlers, and preschoolers discussed in chapter 7 is an example of a study that used a random sampling of households (Rideout, Hamel, & Kaiser Family Foundation, 2006). The study was a random, national telephone survey of families with children ages 6 months to 6 years old. The parent who spent the most time with the child was asked to complete the survey.

Stratified Samples

In a **stratified sample**, participants are deliberately selected from a variety of levels (strata) or subgroups within the population. For example, one study used a stratified, random sample to examine the care received from family members by African American and European American adults ages 65 and older who live in their own homes. The sample groups were selected in proportion to their numbers in the community. Within the African American and European American groups, participants were selected at random (Peek, Coward, & Peek, 2000).

Matched Groups

Researchers can also select two or more groups of participants who are similar on many dimensions. In most studies using **matched groups**, participants in one group receive some type of treatment or participate in some type of experimental intervention that the participants in the other group do not receive or participate in. In other studies, the impact of a naturally occurring difference is examined. For example, a matched group design was used to study the impact of low birth weight on subsequent academic performance. At age 11, children who had weighed less than 750 grams (1.65 pounds) at birth were compared to children who had weighed 750 to 1,400 grams (1.65 to 3.08 pounds) and to children of normal birth weight. The groups were matched on age, sex, and other background variables. The design allowed researchers to evaluate the long-term risks for very small babies (Taylor, Klein, Minich, & Hack, 2000).

Volunteer Samples

Participants can be solicited by asking people directly, placing advertisements in newspapers or on bulletin boards, sending letters to teachers or parents asking for participants, or writing to professionals or groups of potential participants. Those who are included in the study are selected from among those who **volunteer**. Most studies that are conducted with students enrolled in introductory psychology courses involve volunteer samples. Although the students may be required to participate in research, they usually have a choice about the study for which they will volunteer. People can register online to participate in computer-based research. Companies have emerged that provide samples of participants who have volunteered to carry out online studies. Some provide convenience samples of workers who choose which projects they will respond to; other services will identify samples that meet a researcher's specifications (DeSoto, 2016). In some sense, all research with human participants uses a volunteer sample. One cannot compel a person to participate in research.

The Qualitative Approach to Sampling

The primary objective of the qualitative approach to sampling is to learn as much as possible from each informant. Researchers begin with some general idea of questions they seek to understand. The strategy is to remain open to the information that is provided. Researchers may learn that they cannot get information about the question they started out with. For example, in a study of institutional wards for people with severe and profound retardation, Taylor (1987) wanted to know about residents' perspectives. However, many residents were nonverbal, and others were reticent to share their opinions so Taylor shifted his attention to staff perspectives on the environment. Qualitative researchers emphasize that the **informants** should have the knowledge and experience that the researcher requires, be able to reflect and verbalize about the experiences, and be willing to participate in the study. The number of informants or settings in which research occurs is not decided in advance. Typically, the greater the depth and detail in each case, the fewer the cases will be included. Additional cases are added as needed until the researcher believes that the variety of perspectives within a setting has been captured and the theoretical insights are well confirmed (Maxwell, 2009).

Strengths and Weaknesses of Approaches to Sampling

There are both strengths and limitations to the different approaches to sampling. Random sampling and stratified sampling are the most likely to ensure that a sample is representative of the population from which it is drawn. If each person in the population has an equal chance of being included in a study, then the results of the study ought to be equally likely to apply to those in the population who did not participate as to those who did. These sampling approaches provide statistical information about a population. They do not provide information about any specific person within the population. For example, the mean or arithmetic average income of a group of 100 people may not be the exact income of any single person in the group.

The use of matched samples allows one to examine the impact of naturally occurring events—such as unemployment, parental divorce, or low birth weight—that cannot be randomly assigned. By matching participants on a variety of background factors, such as IQ, family income, or birth order, one might be able to detect the impact of these events on emotional, social, or cognitive development. However, critics argue that one cannot match groups perfectly, and one might omit an important variable for which there is no match. For example, in the study described earlier about the impact of low birth weight on school achievement, sibling order was not included in the match. Because we know that firstborns typically do better on tests of academic achievement than siblings born later, this factor might explain more about the outcome than birth weight.

The method that places the greatest limits on generalization is volunteer sampling. One never knows what type of person will volunteer to participate in social science research. Reliance on volunteers may produce special problems. For example, imagine a study that promises to pay $25 to those who participate. People who volunteer to participate in this research may be especially in need of money. Sometimes, volunteers have more free time, are hoping to find some kind of help as a result of participating in the research, or have greater faith in science than those who choose not to volunteer.

Regardless of these limitations, volunteer samples are widely used. Most of the studies cited in this textbook are based on volunteer samples. All studies involving observation, interview, or experimentation with children require formal consent from parents and could be classified as volunteer samples. Frequently, the only way to study a certain question is to ask for volunteers.

Some of the research findings discussed in this text are based on **clinical samples**. The participants have been involved in some type of treatment program or are on a waiting list to receive clinical treatment. These studies are especially important for understanding the causes of clinical conditions, the developmental paths or patterns that these conditions exhibit, or the impact of certain interventions on these conditions. Without voluntary participation, there would be no way to begin to document the effectiveness of treatment. At the same time, one must be cautious not to generalize findings from clinical studies to the population as a whole.

It will come as no surprise that the vast majority of studies reported in U.S. journals are based on U.S. samples. The U.S. population comprises only 5 percent of the world population. Thus, studies that presume to characterize normal development are limited to the extent that the results have not been repeated or confirmed across countries and cultures (Arnett, 2008). As international communication improves and the use of the Internet supports international collaboration, we expect that cross-national research will increase.

Similarly, many studies of development during the period that we refer to as later adolescence are carried out with college students. Since roughly one third of later adolescents do not attend college, the results of these studies cannot be accurately generalized to the noncollege population.

From a qualitative perspective, the best informants are those who willingly volunteer to share their experiences and reflect on them. If the informant is providing an authentic, open narrative, then insights can be drawn. Each informant's perspective is treated as one way of making meaning of the situation. The researcher's job is to try to build a complex picture of the topic by synthesizing and comparing the views of multiple informants.

Research Methods

A variety of methods have been used to study development. Each one has strengths and weaknesses, allowing the investigator to focus on one set of behaviors at the expense of others. The choice of method must fit the problem under study. Six categories of research methods are described here: *observation, case study, interviews, surveys, tests,* and *experimentation*. These methods have all contributed to the discovery of knowledge. Some techniques—especially observation, case study, and interviews—are more commonly used in qualitative inquiry as investigators try to uncover basic themes or dimensions of a problem. Other methods—especially observation using a predetermined coding scheme, experimentation, structured interviews, surveys, and tests—tend to be used in the positivist approach to the research process.

Observation

At the heart of all science is observation—taking note of events and trying to make sense of them. Direct **observation** of children in their home and school environments is one of the oldest methods for studying development (Kessen, 1965). Researchers have used mothers' diaries and observation logs to gather information about behavior in intimate settings that could not be known in any other way. Jean Piaget was guided by the observations of his own children in the formulation of his theory of cognition. Today, researchers conduct observations in homes, schools, playgrounds, and child care centers where children typically spend their time. Others bring children and their families or friends into homelike laboratory settings, where they can watch children's behaviors under more constant and controlled physical conditions (Kochanska, Murray, & Harlan, 2000).

Naturalistic Observation. **Naturalistic observation** refers to research in which behavior in a setting is carefully observed without any other kinds of manipulation. This type of observation, sometimes referred to as **ethnography**, provides insight about how things occur in the real world (Fetterman, 2010). In some instances, researchers go into a setting to observe the full range of interactions and behavior patterns. Based on their field notes, they begin to develop hypotheses about the meaning of the behaviors. Then, they may test these hypotheses through more focused observation or controlled experimentation. In other instances, researchers use observation to examine a specific behavior or relationship. They may be looking for different forms of peer aggression, patterns of social cooperation, or conditions that promote cross-gender interactions. In these studies, the observers limit their observations to behaviors that are relevant to their focus.

Participant Observation. In **participant observation** the researcher actively engages in interactions with other people in a setting in order to understand how they experience the world. To engage in this type of work, one must obtain access to the setting and then gain the trust of the people in the setting. Some participant observation takes place in public settings, such as parks, street corners, pool halls, or train stations, where the researcher can be accepted as a nonthreatening participant. Even in these situations, it may take time for people to interact with the observers or be willing to confide in them. In Elliot Liebow's (1967, 2003) famous study of Black street-corner men, *Tally's Corner*, Liebow met his primary informant, Tally, while playing with a puppy outside a carryout restaurant. The friendship he formed with Tally led to introductions to other men on the street.

The participant observer usually gathers data through field notes, which are made after an observational session. Over time, the skilled observer learns to retain information about the details of a session and to record it in a systematic way. This is a very demanding process; it may take several hours to summarize what was observed in a single hour in the field. In addition to the observations, researchers try to capture their own reactions to the situation, using personal feelings and responses as a way of empathizing with the participants. In a study of a mental institution, Taylor made the following field notes:

> O.C. [observer's comments]: Although I don't show it, I tense up when the residents approach me when they're covered with food or excrement. Maybe this is what the attendants feel and why they often treat the residents as lepers. (Taylor & Bogdan, 1998, p. 73)

One of the challenges in participant observation is to check out and confirm one's insights from observation by comparing them with information drawn from other sources. This is especially important the more involved one becomes in the setting and the more attached one becomes to the participants. This confirmatory approach, called *triangulation*, can be achieved by looking at written documents about the setting, interviewing other informants, and sharing observations with other members of a research team (Taylor & Bogdan, 1998).

Correlation. Observational studies lend themselves to an examination of correlation rather than causation. **Correlation** refers to a statistical analysis of the strength and direction of the relationships among variables. It reflects the degree to which knowing the value of one variable, such as popularity, allows one to predict the level of another variable, such as aggressiveness.

The correlation coefficient is a numeric index of the strength of relationship between variables that can range from a value of +1.0 to −1.0. As an example, consider the correlation between popularity with peers and aggressiveness. If, as popularity increases so does aggressiveness, the correlation is *positive* (between 0 and +1.0). If, as popularity increases, aggressiveness decreases, the correlation is *negative* (between 0 and −1.0). If there is no systematic relationship between aggressiveness and popularity, the correlation is close to 0 (see FIGURE A.2 ▶). A correlation of 0.40 suggests that

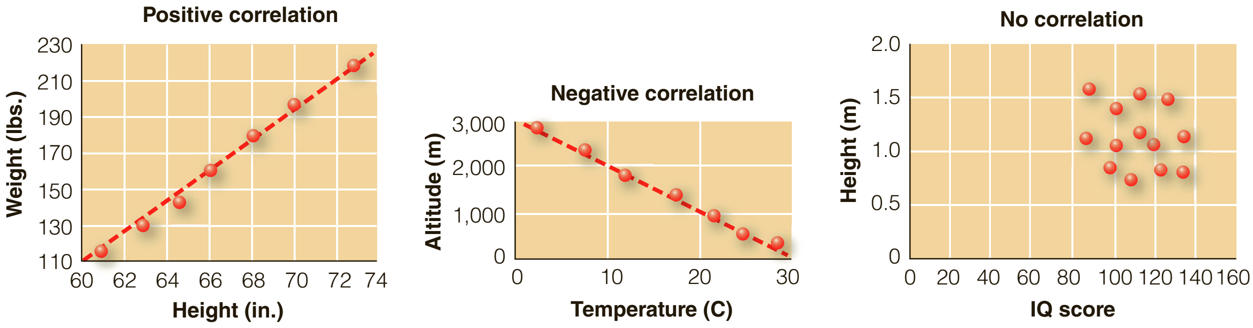

FIGURE A.2 ▶ PATTERNS REFLECTING POSITIVE, NEGATIVE, AND ZERO CORRELATIONS there is a positive relationship between aggressiveness and popularity, but that aggressiveness cannot be predicted entirely or even predominantly by knowing about a person's popularity.

A strong correlation between two variables shows only that there is an association between them. It does not provide information about causation. Knowing that aggression is negatively correlated with popularity does not necessarily mean that being aggressive causes children to be rejected by peers. It could be that some other factor, such as mistrust of others, accounts for both aggression and peer rejection.

Strengths and Limitations of the Observational Method

Many scholars agree that direct observation is an ideal way to study behavior. It avoids the interpretive issues that are raised when one asks people to report on their behavior, and it allows for the documentation of patterns of behavior that may not have been anticipated by the investigator. For example, in studying patterns of dominance among children, one might assume that hitting is a form of dominance. However, in observing play behavior, one may find that certain kinds of hitting are a type of affectionate interaction rather than a mechanism for achieving dominance. The observational method allows participants' behaviors to guide the researcher's conceptualization. Rather than setting up a specific task or group of questions and having people respond, the observer examines the full range of relevant behaviors and builds an interpretation of the meaning of the events from the patterns that have been observed.

Observational research also has weaknesses. It is often difficult to establish agreement among observers about exactly what occurred. Think about the times that you and a friend have been in the same situation but have entirely different reactions to what is happening or describe it very differently to a third party. Typically, two or more observers' codings of the same situation are compared to determine whether different observers interpreted the same event in the same way. This is called **interobserver reliability**. When interobserver reliability is high, one has confidence that all the observers are describing or coding the events in the same way. When interobserver reliability is low, the researchers must determine why and then correct the differences in observation techniques. This may result in changing the category scheme so that it is easier to link each behavior with a category, or it may result in more training, so that the observers know more precisely how to code each behavior.

Another difficulty with the observational method occurs when so much activity is taking place that it is difficult to select specific behaviors or to code fast enough to keep up with the pace of activity in the setting. The technology of video recording has helped address this problem. A video record can be reviewed over and over again. Several observers can watch a video, stop it, and discuss what they saw. The same events can be observed from several points of view. Video records allow one to track the sequences of interaction, turn taking, and the formation of cycles of interaction among family members, which often occur too subtly or quickly to be captured by direct observation (Heath, Hindmarsh, & Luff, 2010; Johnson, Cowan, & Cowan, 1999). Because of the rich potential for sharing and reusing video files for different research purposes, the National Science Foundation and the National Institutes of Health have created a web-based video library, Databrary. This resource will preserve recordings relevant for developmental research and encourage their reuse (Adolph, 2016).

Some research focuses on a particular kind of behavior or behavioral sequence, such as helping behavior, peer rejection, or conflict. In naturalistic observation, one cannot be sure that the behavior of interest will take place during the observational period. Finally, some researchers fear that the presence of the observer or the introduction of audio recording, videotaping, or even note taking, may change the nature of the behaviors that take place in the setting. Although there are techniques to limit the impact of the observer on the setting, this is always a concern in direct observation.

Case Study

A **case study** is an in-depth description of a single person, family, social group, or social setting. The purpose of a case study may be to illuminate something very particular and interesting about the person or organization being studied, illustrate a general principle by providing specific details, examine a phenomenon that does not conform to theoretical predictions, or stimulate theory development in an area that has not been investigated (Yin, 2014).

Some case studies document the lives of great individuals. In *Gandhi's Truth*, Erikson (1969) provided a psychosocial analysis of the life of Mahatma Gandhi. Erikson considered Gandhi's childhood, adolescence, and young adulthood as they contributed to his personality, his moral philosophy, and the contradictions between his personal relationships and his role as a powerful social leader.

Case studies can also focus on social groups, families, and organizations. One of Anna Freud's most famous cases described the attachments that developed among a group of orphans who had lived together in a concentration camp during World War II (Freud & Dann, 1951). The study focused on the strong feelings the children had for one another and their strategies for maintaining their sense of connectedness once they were placed in a more normal social environment. The case illustrated a unique phenomenon—the intense emotional attachment of young children to each other—that had not been documented before.

Case studies can be based on a variety of sources of information, including interviews, therapy sessions, prolonged observation, narrative stories, diaries or journals, letters, historical documents, and talks with people who know the subject of the study. The researcher usually spends a great deal of time with the subject of the case, in conversation, observation, and gathering information from documents and informants. In addition to gathering information, the researcher engages in ongoing reflection in order to reach a new depth of insight about the case.

Strengths and Limitations of the Case Study Method

Case studies have the advantage of illustrating the complexity and uniqueness of the subject. Studies carried out with large samples often identify general principles, whereas case studies provide concrete examples of how these principles play out in the lives of specific individuals or groups. Some cases give the details of an experience that is rare and might not be captured in a large-scale study. Sometimes, the case study brings a problem to the attention of researchers, who then pursue it through other methods. Although case studies cannot provide the basis for broad generalizations, they can provide specific examples of instances where a broad generalization does not hold true. Throughout this book, you will find case material that is intended to help you apply concepts from the text to specific examples and to stimulate reflection about links among theory, research, and your own life experiences.

Case studies have been criticized as unscientific. They are obviously not representative of large groups of individuals. Moreover, if the information that provides the basis of the case study is gathered in a biased or subjective way, then the results or conclusions of the study will be of little worth. Of course, this criticism applies to any type of research. Critics argue that there is no reliability in case studies. If different people were writing a case study on the same individual, they might come up with very different views of the events and their significance.

One must have a very clear idea of the study's purpose and a systematic approach to gathering information in order to conduct case studies that meet the standards of scientific observation. At the same time, vividly written, compelling case material has had a consistent impact in stimulating theory and research in the field of development. In some instances, the lucid recounting of case material is more convincing to policymakers than the results of studies based on large, national samples.

Interviews

Many case studies are based on face-to-face interviews. The **interview** method can also be used to gather data from large numbers of individuals or from individuals in clinical settings. Interviews can be highly structured, almost like a verbal survey, or very open ended, allowing the participant to respond freely to general questions. There are at least three common uses of in-depth interviewing (Roulston, 2010). First, the life history or personal narrative allows the researcher to learn about a person's key life experiences and the meaning of those experiences. The researcher's role is to encourage the person being interviewed to cover all the important issues and to foster elaboration and reflection.

Second, through interviews, informants are asked to describe in detail events that occurred when the researcher was not present. This might be a historical event, a natural disaster, or the behaviors of a group to which the researcher does not have access. For example, a researcher may want to interview informants who have been members of a gang about the gang's initiation rites or practices. Third, interviews can be useful in gathering information from a number of people about a similar topic. For example, Harrington and Boardman (2000) interviewed 100 people whom they called pathmakers—people who achieved career success despite growing up in impoverished families and communities.

The success of the interview method depends heavily on the skill of the interviewer. Interviewers are trained to be nonjudgmental as they listen to a participant's responses. They try to create **rapport** with the participant by conveying a feeling of trustworthiness and acceptance. The goal, especially in qualitative interviewing, is to create a conversational atmosphere where the person feels at ease to talk. In unstructured interviews, the interviewer makes use of this rapport to encourage the participant to say more about a topic and to share thoughts that may be private or personal. Matching the race and gender of the interviewer and the participant being interviewed has been found to help foster rapport and improve the quality of the data that are produced.

The interview method has traditionally been associated with clinical research; however, it is becoming a common method in the study of cognition and language as well. Piaget's structured interview technique (Piaget, 1929) provided a model for the investigation of cognitive development. The researcher who uses this technique asks a child a question (e.g., "Are clouds living or dead?") and then follows up on the child's answer with questions about how the child arrived at his or her conclusion. In other studies, Piaget asked children to solve a problem and then asked them to explain how they arrived at the solution. The child becomes an informant about his or her own conceptual capacities. This approach has been adapted in the study of moral development, interpersonal development, and positive, helping behavior.

Strengths and Limitations of the Interview Method

The interview method has the advantage of allowing individuals to contribute their own views on the topic being studied. They can tell the interviewer what is important to them, why they might choose one alternative over another, or what they think is wrong with the investigator's view of the situation. Interviews have the advantage of expediency when it might be difficult to gain access to a setting for observation or when one wants to gather information from a larger number of participants, rather than observing just a few.

There are also limitations to the interview method. Participants may present themselves in the way they want the interviewer to see them. This is referred to as **self-presentation bias**. Young children's responses are especially vulnerable to influence by the interviewer. By smiling, nodding, frowning, or looking away, the interviewer can deliberately or inadvertently communicate approval or disapproval. There is a fine line between establishing rapport and influencing responses.

Another limitation of interviews is that people may not be aware of all the factors that influence their behaviors or decisions. Thus, in asking people about their lives and why they behave as they do, one is limited by the participants' level of insight into their own situation. As compared to participant observation, relying solely on interviews limits the researcher's access to contextual factors that may influence a person's behavior (Taylor & Bogdan, 1998).

Surveys and Tests

Survey research is a means of collecting specific information from a large number of participants (Fowler, 2013). If people are to respond directly to surveys, they must be able to read and write unless the survey questions are read to them. The survey method is, therefore, most commonly used with participants in middle childhood, adolescence, and adulthood. However, survey information about infants and toddlers is often collected from parents, child care workers, physicians, nurses, and others who are responsible for meeting the needs of young children. Surveys have contributed a great deal to our knowledge about the way adults perceive the behaviors and needs of young children.

Survey methods can be used to collect information about attitudes ("Do you believe teachers should be permitted to use corporal punishment with their students?"), current behaviors and practices ("How many hours per day do you watch television?"), aspirations ("What do you hope to do when you graduate from high school?"), and perceptions ("How well does your mother/father or son/daughter understand your views?").

Survey questions are prepared in a standard form, and the responses are usually coded according to a prearranged set of categories. In well-designed surveys, the questions are stated clearly and offer response choices that are not ambiguous or overlapping. Surveys may be conducted by telephone, through the mail, on the Internet, in classrooms, at work, or in the participants' homes (Fowler, 2013).

Tests are often similar in form to surveys. They consist of groups of questions or problems that the person is expected to answer. Usually, tests are designed to measure a specific ability or characteristic. You are no doubt familiar with the kinds of tests typically given in school. You are presented with a group of items and asked to produce the correct answer or select the correct answer from among several choices. Intelligence and achievement tests are of this nature. A researcher might give these tests along with some other measures in order to learn how intelligence relates to social life, emotions, or self-understanding.

Other tests are designed to measure specific psychological constructs such as creativity, conformity, depression, or extroversion. Some tests are administered to assess whether a person has some form of mental illness, learning disorder, or developmental or physical disability.

Psychological tests must be reliable and valid to be useful. Tests are **reliable** when the results are consistent. A person who takes a reliable test on two consecutive days should get approximately the same score on both days, unless some deliberate training or intervention has been introduced between test sessions. There ought to be a positive correlation (between 0 and +1.0) between the two scores.

Tests are **valid** when they measure what they claim to measure. The people who design the tests have to define what it is they are trying to measure. They also have to provide evidence that their test really measures this construct (Ray, 2011). For example, when designing a test to measure self-esteem, one should first consider, "What is meant by self-esteem?" and "What type of questions or tasks would provide evidence of self-esteem?"

Consider the various tests that have been designed to measure intelligence in infants and very young children. The results of these tests are not very closely related to the results of tests of intelligence given in adolescence and adulthood (Slater, Carrick, Bell, & Roberts, 1999). In other words, infant intelligence tests are not valid measures of intelligence for older children or adults. The infant tests are not really tests of broad, adaptive intelligence, but measures of sensory processing and central nervous system coordination.

Strengths and Limitations of Surveys and Tests

Surveys and tests have advantages that make them widely used in developmental research. They allow the summary and comparison of responses by large groups of respondents. Surveys and tests have been designed to address a wide variety of topics. With a prearranged coding or scoring system, many tests can be administered and evaluated without the extensive training that is usually necessary with observation or interview methods.

This method also has limitations. Some surveys create attitudes where none existed before. This is referred to as the **reactive** nature of surveys. For example, you might ask sixth-grade children questions about their satisfaction with their school curriculum. The students may answer a lot of questions on this topic, even though they had not given much thought to the issue before. Thus, reading the questions and response options on a survey may influence participants to formulate their opinions (Wilson, LaFleur, & Anderson, 1996).

Another problem is the gap between answers to survey questions or scores on tests and actual behavior. Parents may respond to a survey by indicating that they allow their children to participate in family decisions, but when it comes to real family decisions, they may not give their children much voice. Some survey questions are more difficult for some respondents to answer accurately than others. For example, consider the following question: "How often did you go for medical treatment over the past 6 months?" It would be easier for a person who went only once to respond accurately and with confidence than for a person who went six or eight times (Mathiowetz, 1999).

Experimentation

Experimentation is best suited for examining causal relationships. In an **experiment**, some variable or group of variables is systematically manipulated to examine the effect on an outcome. For example, in research on memory among older adults, the complexity of the material and the speed of presentation are varied in order to learn more about how these factors influence the ability of adults to recall information. The factor (or factors) manipulated by the experimenter is called the **independent variable**. The dimension of the participant's responses or reactions that is measured is the **dependent variable**. The research is carried out to determine whether the independent variable or some combination of independent variables can produce a change in the dependent variable.

In some experiments, one group of participants has a certain set of experiences or receives information (usually referred to as a **treatment**) that is not provided to another group. The group that experiences the experimenter's manipulation is called the **experimental group**. The group that does not experience the treatment or manipulation is called the **control group**. Participants are randomly assigned to the treatment and control groups so that differences in their behavior can be attributed to the treatment. For example, in a study of academic performance in human development courses, some students enrolled in a course are randomly assigned to the experimental group, in which they are linked as a study group through email, so they can contact one another, discuss questions from the course, and share their ideas. Other students, who are in the control group, do not receive this

Internet support. Differences in course grades between the experimental and the control groups would be attributed to the Internet intervention.

In other experiments, the behavior of a single group of participants is compared before and after a treatment or across several treatments. Once again, systematic differences in behavior before and after the treatment are attributed to the experimental manipulation. In this case, each participant serves as his or her own control.

Control is the key to successful experimentation. The experimenter exercises control in selecting the participants who must be able to bring equivalent competencies to the situation. The task presentation must be the same for the experimental and the control group. If these conditions are not met, one cannot assume that differences between groups are due to the treatment.

Many studies in human development are **quasi-experimental**. This means that the treatment was not controlled by the experimenter but was the result of some life events (Fife-Shaw, 2012). Suppose we are interested in the impact of unemployment on conflict between married couples. We cannot (nor do we want to) cause some adults to lose their jobs while others remain employed. We can, however, compare couples of about the same age and social class who have experienced unemployment with couples who have not. In these studies, assignment to a treatment occurs as a result of real-world events. One would select participants for the study who are as much alike as possible (e.g. a matched sample), except for their encounters with unemployment. It is the task of the researcher to compare some of the consequences of this treatment—the experience of unemployment—and to address the limitations that are imposed on the results because of how individuals come to be in one group or the other.

Strengths and Limitations of the Experimental Method

The experimental method has the advantage of providing conclusions about causal relationships. If the results suggest that the participants' behavior changes only when something about the experimental situation changes, we can conclude that the manipulation caused the changes. This is a very powerful statement, particularly as we search for explanations for how conditions that occur early in development might influence later outcomes.

Experiments also have limitations. Despite careful control, one cannot entirely rule out factors that can interfere with the impact of the treatment or that influence the respondents in ways that were not anticipated (Ray, 1993). In studies on the impact of Head Start, researchers wanted to compare the cognitive performance of children who were and were not enrolled in Head Start. However, it was impossible to control for the diverse educational experiences of children who were not in Head Start. Some enrolled in other early childhood programs; some enrolled in a different Head Start when an opening came up later in the school year; and some attended family child care with an adult who emphasized educational activities (Cooper & Lanza, 2014). Any factor occurring outside the specific design of the study that influences the participants' responses is a threat to the **internal validity** or meaningfulness of the experiment.

Experiments may also be challenged on the basis of their **external validity**. We cannot be certain how applicable a controlled laboratory situation is to the real world. For example, through studies of infant attachment we have learned that infants and young children do not behave the same way in the presence of their mothers as they do when their mothers are absent. Thus, experimental research conducted with children that does not allow their mothers to be present may produce behaviors that differ in quantity, quality, and sequence from the behavior that would be observed under conditions when the mothers are present.

Experimental studies suggest that event A causes response B. In many domains of development, however, a multifaceted, reciprocal process promotes change. Think about the development of *friendship*. A friendship depends on so many domains and on the fit or lack of fit along each domain for the two people. Friendships may be influenced by physical appearance, abilities, temperaments, intelligence, family background, whether others support the friendship or ridicule it, and so on. Friendships are sustained and promoted by continuous feedback and interaction among the friends rather than by one or two factors that could be said to promote or inhibit friendship. Experiments tend to suggest a unidirectional, causal explanation for behaviors that may more accurately be described using an interactional model.

Advantages and disadvantages of the five research methods are summarized in Table A.1.

Designs for Studying Development

The primary concern of developmental research is to describe and account for patterns of continuity and change over time, including explanations for why individuals who have been exposed to similar life situations differ from one another as they age. This challenging task requires strategies for considering changing individuals in changing environments. Four major research approaches have been created for examining development: *retrospective studies, cross-sectional studies, longitudinal studies,* and *cohort sequential studies.*

Retrospective Studies

Retrospective studies ask participants to report on experiences from an earlier time in their lives. Many early studies of childrearing used parents' recollections of their parenting techniques to evaluate their patterns of child care. Researchers who studied the effects of stress during pregnancy often asked women to recall their emotional state before, during, and after their child was born. Investigators of personality development use retrospective data by asking adolescent or adult subjects to recall important events of their childhood.

This approach produces a record of what a person has retained of past events. We cannot be certain that these events really occurred as they are remembered or, for that matter,

Table A.1 Advantages and Disadvantages of the Methods of Developmental Research

Method	Definition	Advantages	Disadvantages
Observation	Systematic recording of behavior	Documents the variety of ongoing behavior; captures what happens naturally, without intervention	Time consuming: difficult to achieve inter-rater agreement; requires careful training; observer may interfere with what would normally occur; difficult to capture and code full range of ongoing activity
Case Study	In-depth description of a single person, family, or group	Focuses on complexity and unique experiences of individual; permits analysis of unusual cases	Lacks generalizability; conclusions may reflect bias of investigator; hard to replicate
Interviews	Face-to-face interaction in which each person can give a full account of his or her views	Provides complex, first-person account; flexible method; allows access to the other person's own meaning	Vulnerable to investigator bias; self-presentation bias; relies on participant's self-insight
Surveys and Tests	Standard questions administered to many participants	Permits data collection from large samples; permits group comparisons of responses in standard form; requires little training; flexible	Wording and way of presenting questions may influence responses; responses may not be closely related to behavior; tests may not be valid for certain groups
Experimentation	Analysis of cause–effects relations; manipulation of some conditions while others are held constant	Permits testing of causal hypotheses; permits isolation and control of specific variables; allows evaluation of treatment effects	Laboratory findings may lack ecological validity; unable to control for all threats to internal validity; focuses on a unidirectional model of causality

whether they occurred at all. Piaget (1951) described a vivid memory from his second year of life:

> I was sitting in my pram, which my nurse was pushing in the Champs Elysées, when a man tried to kidnap me. I was held in by the strap fastened around me while my nurse bravely tried to stand between me and the thief. She received various scratches, and I can still see vaguely those on her face. (Piaget, 1951, p. 188)

Thirteen years later, when Piaget was 15, the nurse joined a religious order. She wrote to his parents and returned a watch they had given her for protecting Jean from the kidnapper. She confessed that she had made up the story, even to the point of scratching her own face. Piaget believed he created the visual memory from the story his parents had told him.

The passage of time may change the significance of past events in a person's memory. As we gain new levels of cognitive complexity or change our attitudes, we reorganize our memories of the past so as to bring them into line with our current level of understanding (Kotre, 1995b). Sometimes, people claim to have recovered memories of past events that have been long forgotten or repressed. It is difficult to determine the accuracy of these memories (Loftus, 1993). They may be entangled with current experiences or with ideas taken from books, movies, or conversations with others. They may be altered by the suggestion that something happened that actually did not, or by the suggestion that something did not happen that actually did. Because memory is easily modified by suggestion, its usefulness in uncovering systematic data about the past is limited. However, retrospective data provide insight into how people make sense of their past and the role they give to past experiences in determining their present way of thinking. Studies that use the technique of life review provide insight into the way adults organize and structure key periods and events from their life history (McAdams et al., 1997).

Cross-Sectional Studies

Studies that compare people of different ages, social backgrounds, or from different school or community settings are called **cross-sectional studies**. Such studies are quite common. Investigators may compare children at different levels of biological maturity or different chronological ages to learn how a particular developmental domain changes with age. The main limitation of the cross-sectional method is that it measures group differences, not patterns of individual change over time. However, these group differences are interpreted to suggest a pattern of development. With respect to studies on cognitive problem solving, the cross-sectional approach tells us that most 12-year-olds are more flexible in their reasoning than most 7-year-olds. It does not tell us how the same children actually change from the time they are 7 until they are 12 or how the children who were most flexible at age 7 would perform at age 12 in comparison with those who were the least flexible.

Longitudinal Studies

A **longitudinal study** involves repeated observations of the same participants at different times. The time between observations may be brief, as from immediately after birth to 2 or 3 days after birth. Observations may be repeated over the entire life course, as in Leo Terman's longitudinal study of gifted children (Crosnoe &

Elder, 2004; Holahan, Sears, & Cronbach, 1995; Sears & Barbee, 1978; Terman & Oden, 1947, 1959).

An emerging approach to longitudinal research is called the *intensive longitudinal method.* Using a smartphone, for example, participants can be prompted to respond many times a day, wherever they are. Physiological, psychological, and environmental information can be gathered repeatedly to produce a personalized network of data that can create a portrait of a person's fluctuating activities, moods, or stress levels. The results of this type of intensive longitudinal data can be useful in identifying subtle patterns of individual stability or change such as emotional state fluctuations or the relationship of activity and mood (Drew, 2016).

Longitudinal studies have the advantage of tracking the course of development. We can discover how certain characteristics of children in infancy or toddlerhood relate to those same characteristics when the individuals reach adolescence or adulthood. We can learn whether certain qualities of childhood, such as intelligence or sociability , are related to overall social adjustment or life satisfaction in later years. Longitudinal studies permit us to trace intra-individual patterns over time—that is, how individuals change, for example, from the use of one-word expressions to two-word phrases. They also allow us to monitor changes in groups, for example, by comparing adults who have children in their early 20s to those who remain childfree and looking at their economic or occupational attainment by midlife (Schaie, 1994).

Longitudinal studies may be difficult to complete, especially if they are intended to cover a significant time period, such as the years from childhood to adulthood. Over this span of time, participants may drop out of the study, the investigators may lose funding or interest in the project, or the methods may become outdated. Questions that once seemed important may no longer be seen as vital. Another limitation is that repeated interactions with the participants may influence their behaviors. Participation in the study could itself become a factor in their development. One of the greatest limitations of longitudinal studies is that they focus on only one generation or cohort of participants. Imagine studying the academic achievement and occupational attainment of a group of children born in 1980. Historical and social factors that may influence the course of this group's development will be inextricably intertwined in the observations. One cannot tell if people growing up at other times in history would exhibit the pattern of changes that characterize this particular group.

Cohort Sequential Studies

A **cohort sequential design** combines the cross-sectional and longitudinal approaches into one method of study (Prinzie & Onghena, 2005; Schaie, 1965, 1992). Groups of participants, called *cohorts*, are selected because they are a certain number of years apart in age. For example, imagine a study that begins with three groups of adolescents who are 11, 14, and 17, respectively. Every 3 years, these groups would be interviewed until the 11-year-olds have turned 17. Every 3 years, a new group of 11-year-olds would be added to the study. This combination of a longitudinal and cross-sectional design is a powerful developmental research method. It produces immediate cross-sectional data, longitudinal data after 3 and 6 years, and a comparison of children who were the same age (11, 14, or 17) at three different times. This third comparison allows one to identify social and historical factors that may influence age-related differences. This comparison also provides control for the possible impact of repeated measurement on the participants.

FIGURE A.3 ▶ THE COHORT SEQUENTIAL DESIGN

Comparisons of cohorts over time offers a way of controlling for the many historical factors—such as access to schooling, health, medical treatment, and nutrition—that might influence performance by separating these factors from age-related changes. The elements of a cohort sequential design are shown in FIGURE A.3.▶ One drawback to the cohort sequential design is that data analysis requires more complex techniques in which time of response and frequency of response can both be included.

Evaluating Existing Research

In addition to collecting new data, considerable scholarly effort is directed to reviewing and evaluating existing research. As a student, you may be asked to review research findings on a topic of interest to you. You will probably rely on online databases to find books, book chapters, and journal articles relevant to your topic. These sources provide information from published sources, many of which have undergone a **peer review** process. This means that other professionals have read and critically evaluated the materials before they were published. You may also find information using Internet search engines. Internet resources are of a much more varied nature, including Web pages from professionals, reports of research institutes and centers, government documents, and blogs from teachers, students, and others who have opinions on the topic. The challenge in reviewing all this information is to apply a standard for judging its quality and validity as you formulate your own analysis of the topic.

Most researchers use this method of reading and reviewing the research of others to keep well informed about the research in their subject area. They analyze the work of others to generate new questions and to formulate well-founded conclusions about issues in their field of specialization. The study, analysis, and evaluation of current research literature constitute special skills in their own right (Fink, 2013).

The evaluation of published research poses its own challenges. Recent reports of research fraud alert us to the hazards of relying too heavily on the results of any one specific study. For example, the Dutch researcher, Diederik Stapel was found to have made up the data for 55 published studies (Cossins, 2012). The scientific process argues for relying on replications to ensure that a research finding is credible. However, relatively few published articles are replications (Pashler & Wagenmakers, 2012). Research journals tend to have a bias toward publishing novel, unexpected, and possibly media-noteworthy results. This may increase the tendency of scholars to focus their research on the unexpected or surprising results rather than the replication of prior studies. Many journals will not publish "null findings." In other words, studies, including replications, that do not find statistically significant results are unlikely to be published (Ferguson & Heene, 2012; Shea, 2011). Recent efforts by scientific associations have encouraged the publication of replications in order to build a more trustworthy knowledge base.

The approaches to statistical analyses of data have become so complicated that only a small group of experts can really evaluate whether the techniques have been used properly. Critics have suggested that researchers should be required to state the analytic technique they plan to use before conducting the research in order to prevent post-hoc manipulations that disguise the basic results of the research (Wagenmakers, Wetzels, Bosboom, Van der Maas, & Kievit, 2012).

Increasingly, websites provide information for researchers and report results of research. Because of the open access nature of the Web, there is no guarantee about the quality or validity of information. Using information from the Web requires a degree of care and caution over and above that used in the review of peer-reviewed journals. In reading about research from a website, one should ask the same questions about the research process that one would ask of a peer-reviewed journal article. In addition, the following issues need to be considered when evaluating Web-based information: the authority and **credibility** of the authors of the Web-based information; the scope, relevance, and timeliness of the information; and the potential **bias** of the author's point of view.

Authority and Credibility

- Who publishes the website?
- Who is the author(s) of the website?
- What makes the author an authority on this subject?
- Does the author cite his/her experience/credentials?
- Does the website contain footnotes or references?
- If so, does material taken from other sources appear to be fully credited?

Scope, Relevance, and Timeliness

- Who is the intended audience? (general, specialized, scholars)
- What is the level of the material? (basic, advanced)
- Is new research being reported or is the author reviewing/summarizing previously conducted research?
- What time period is covered?
- How recently has the website been updated?

Bias and Accuracy

- How is the information presented? (fact, opinion, propaganda, etc.)
- If presented as fact, is it accurate?
- Is there a bias? (cultural, political, religious, etc.)
- If so, is the bias clearly stated or acknowledged by the authors?

One strategy in making use of Web-based information is to look for several sources on the same topic.

There are some wonderful resources of online information. You have come across many of them cited as references throughout this book. All branches of the federal government have websites with information about policies, programs, and research reports. The U.S. Census Bureau publishes extensive reports on a range of topics of interest in human development including population trends, household characteristics, labor market trends, and health. Medical information is available from the National Institutes of Health as well as from ongoing medical research projects that provide results of their research online. The Bureau of Labor Statistics provides information on employment, occupational opportunities, and career trends. The Administration on Aging is a rich resource for programs, services, and surveys of older adults. Advocacy groups, such as the National Center for Children in Poverty, provide up-to-date information about the impact of policies or programs.

Beyond the United States, there are websites from other countries and sources about international trends such as the World Health Organization. The United Nations monitors international trends such as child poverty, women's rights, and access to education. With all this information available, the research process is at once more open, more accessible, and more vulnerable to viral mischief, just like an election. The effectiveness of your searches will depend on the way you define the topic of interest, your patience in visiting a variety of sources, and your critical evaluation of the quality of information you uncover.

Ethics

Ethics refers to principles of conduct that are founded on a society's moral code. In conducting research with living beings, and especially with children, social scientists continually confront ethical questions. Researchers are obligated to maintain humane, morally acceptable treatment of all living study participants.

Three reports have influenced the conceptualization of ethical guidelines for research with human participants: The Declaration of Helsinki (1964), the Belmont Report (1979), and the International Ethical Guidelines for Biomedical Research Involving Human Subjects (1993). Five key dimensions emerged from these three documents that provide a framework for ethical medical and behavioral research (Presidential Commission for the Study of Bioethical Issues, 2015; Yan & Munir, 2004):

1. Human rights: The fundamental right for human well-being where each can achieve his/her full potential.
2. Validity: Accuracy and closeness to the stated scientific goals.
3. Distributive justice: The fair distribution of research benefits and risks.
4. Beneficence/nonmaleficence: The obligation to maximize benefits and minimize risks.
5. Autonomy: The permission granted by subjects to allow research.

The American Psychological Association has published a guide for researchers entitled *Ethics in Research with Human Participants* (American Psychological Association, 2002; Sales & Folkman, 2000). This guide provides advice to researchers about how to manage all aspects of the research process in order to maintain the trust and safety of participants. Participants have a right to know how their **privacy** will be preserved and what steps will be taken to ensure that responses or behaviors observed in the research will remain **confidential**. The guidelines require that participants be told about all aspects of the research that may influence their decision to participate. This is referred to as **informed consent**. Individuals must not be coerced into participating in a research project, and their refusal to participate should have no negative consequences. If children in a classroom decide that they do not want to participate in a research project, or if their parents do not give permission for them to participate, they should not be shamed, given an undesirable alternate assignment, or given a lower grade.

Researchers must protect participants from unnecessary painful physical and emotional experiences, including shame, failure, and social rejection. Researchers must weigh the benefits of the new information they may discover in a particular study against the potential risks or harm to the participants. Two questions must guide the researcher's decisions:

1. How would you feel if you or one of your family members were a participant in this study?
2. Can the problem be studied in ways that do not involve pain, deception, or emotional or physical stress?

These questions are especially relevant for studies involving young children where it may not be easy to know how stressful or anxiety-provoking an experimental procedure is. For some children, just going into the laboratory setting may be stressful. For some adolescents, being observed in a decision-making situation with peers may be stressful. For some couples, being asked to resolve a conflict in the presence of observers may be anxiety-provoking. Participants must be aware of the fact that they are free to withdraw from the study at any time. They are entitled to a full explanation of the study once it has been completed. When the participants are children, their parents must be given this information and must approve their children's participation.

In thinking about research in the field of human development, certain of the basic principles may conflict. For example, on the one hand, children and those with significant developmental disabilities may not be able to fully understand the nature of the research in order to provide informed consent to participate. As a result, decisions may be made to eliminate these groups from research or to impose strict limitations on their participation in order to protect them from harm. On the other hand, these vulnerable populations may be the ones most likely to benefit from research. By preventing research that focuses on these populations, they may be less likely to benefit from new practices, interventions, or basic knowledge (Yan & Munir, 2012).

When children under the age of 18 are involved as research participants, it is typically the practice to require a parent or guardian to provide consent. However, researchers need to be sensitive to cultural patterns and practices regarding parental authority and community responsibility for children. In some Native American tribes, the tribal leader has authority to make decisions about whether children can be included in research. In some African American families, grandparents, aunts, uncles, or older siblings may be the primary decision makers even if they are not legal guardians. They need to be consulted concerning a child's participation in research. In these examples, a person who is responsible for the child's protection may not be the child's legal guardian (Fisher et al., 2002).

Researchers are obligated to stipulate **conflicts of interest** and to avoid them wherever possible. Conflict of interest can arise when a researcher has a financial or personal investment that might influence his or her judgment. Since publication of research is an expectation for faculty promotion and tenure in most universities, faculty members are typically highly motivated to conduct research that can be published. They may fail to give people an accurate description of the time, effort, or risks of participation involved in their study when recruiting participants. They may be tempted to design studies in which recruitment of participants is most easily and quickly accomplished.

In addition to violations of ethical practices regarding the treatment of human participants, some researchers engage in questionable practices that undermine the credibility of their work and violate the principles that ensure accuracy of scientific knowledge. These practices include **plagiarism**, which involves the use of written material by others without providing credit or citation of their work in the application for funding or in a written report; failure to cite studies that do not confirm the author's hypotheses; falsification by modifying or deleting data that alter the statistical significance of the findings; or failing to give credit to students or colleagues who contributed in important ways to the design, implementation, or written report of the research (John, Loewenstein, & Prelec, 2010; Rapp, 2016).

Each university has an **institutional review** process that applies guidelines for the ethical conduct of research to proposals being prepared by faculty and students. Before a study can begin, the institutional review board considers the design of the study and its potential impact on participants and the potential conflicts of interest identified by the investigators. The investigators have to commit to a procedure of informed consent, so that participants are aware of the nature of the research, potential risks, conditions of confidentiality, and their freedom to withdraw from the study at any time if they choose. Approval for the research is typically given for 1 year. The institutional review process includes a mechanism for ongoing evaluation of research that takes place over longer periods of time. Most schools, child care centers, hospitals, nursing homes, and other treatment centers have their own review procedures for determining whether they will permit research to be carried out with the people in their programs. Ethical guidelines are important in order to prevent exploitation of participants and to prevent unintended negative consequences of participation in research. In cases when the results of published research reports have been challenged and misconduct has been proven, the researcher may be required to withdraw prior research from publication sites.

Glossary

abortion Termination of a pregnancy before the fetus is capable of surviving outside the uterus.

accommodation (1) In Piaget's theory of cognitive development, the process of changing existing schemes in order to account for novel elements in the object or the event. (2) In vision, changes in the curvature of the lens in response to the distance of the stimulus.

active engagement Continuing to be sociable and involved in doing things as you get older.

active euthanasia Activities—such as mercy killing or physician-assisted suicide—that are designed to end a person's life, often to end a person's suffering.

activities of daily living (ADLs) Basic types of self-care that are required to function independently.

adaptation (1) In evolutionary theory, the total process of change in response to environmental conditions. (2) In Piaget's theory of cognitive development, a process of gradually modifying existing schemes and operations in order to take into account changes or discrepancies between what is known and what is being experienced.

adaptive leadership A leadership style that is required when an organization faces new conditions or complex problems that cannot be solved with the current use of technologies or techniques. Leaders help frame new ways of defining problems and engaging workers, consumers, or clients in a search for solutions.

adaptive self-organization The process by which an open system retains its essential identity when confronted with new and constant environmental conditions. It creates new substructures, revises the relationships among components, and establishes new, higher levels of organization that coordinate existing substructures.

adaptive self-regulation Adjustments made by an operating system in which feedback mechanisms identify and respond to environmental changes in order to maintain and enhance the functioning of the system.

adequacy versus vulnerability A two-dimensional spectrum of cultural attitudes toward pregnant women. Adequacy is the idea that pregnancy is a sign of sexual prowess and a means of access to social status. Vulnerability is the idea that child-making is exhausting, pregnant women are vulnerable, and women grow more frail with each pregnancy. Combined with solicitude versus shame, these attitudes create a matrix within which the birth culture of any society or subculture can be located.

adolescent pregnancy When a woman becomes pregnant under age 19.

adoption An alternative to biological reproduction for those who believe that there are already enough children who need families and for those who have tried alternative reproductive technologies to no avail.

advance directive A document that allows people to say what type of care they want to receive in case they cannot speak for themselves.

advocate (plural: advocates) A person who pleads another's cause.

affect (plural: affects) Emotion, feeling, or mood.

affiliative value The values placed on helping or pleasing others, reflected in the amount of time spent in and the degree of satisfaction achieved from such actions.

age changes Changes that are due to the natural aging process.

age differences In the comparison of age groups, differences between populations that may be due to development, aging, or a variety of cohort-related opportunities and experiences.

age-graded expectations Views held within societies about what would be appropriate behavior at a given time in life.

ageism A devaluation of older adults by the social community.

agency Viewing the self as the originator of action.

aggressive-rejected A path to peer rejection in which children are aggressive and attribute hostile intentions to others.

aggressive-withdrawn A path to peer rejection in which children are both aggressive and self-conscious.

alcohol and drug use The illegal use of alcohol and/or drugs.

alienation Withdrawal or separation of people or their affections from an object or position of former attachment.

allele (plural: alleles) The alternate state of a gene at a given locus.

Alzheimer's disease The most common form of chronic organic brain syndrome, involving gradual brain failure over a period of 7 to 10 years.

ambiguous loss A condition in which death is uncertain because there is no verification of death, as when a soldier is missing in action and there is no body, or when a person is physically present but unable to participate in any meaningful way in interactions with others.

amniocentesis The surgical insertion of a hollow needle through the abdominal wall and into the uterus of a pregnant woman to obtain fluid for the determination of sex or chromosomal abnormality of the fetus.

amniotic sac A thin membrane forming a closed sac around the embryo that contains a fluid in which the embryo is immersed.

anal stage In psychosexual theory, a period of life in which the anus is the most sexualized body part, typically during the second year of life.

androgens General term for male sex hormones, the most prevalent of which is testosterone.

androgyny The capacity to express both masculine and feminine characteristics as the situation demands.

anomaly Irregularity, something that is inconsistent with the normal condition; abnormality.

anorexia nervosa An emotional disorder in which the person loses the ability to regulate eating behavior; the person is obsessed with a fear of being overweight and avoids food or becomes nauseated after eating.

Apgar scoring method Assessment method of the newborn based on heart rate, respiration, muscle tone, response to stimulation, and skin color.

aphasia A language impairment involving the loss of ability to understand or use speech.

applied behavioral analysis An intervention that uses systematic operant-conditioning strategies to assist people who have severe behavior problems, including aggressive disorders and autism.

appraisal In coping, an estimate of the nature, quality, and importance of the stressors in a situation.

artificial insemination Injection of donor sperm into a woman's vagina to promote conception.

assimilation In Piaget's theory of cognitive development, the process of incorporating objects or events into existing schemes.

assisted living Housing or living arrangements for the elderly, infirm, or disabled, in which housekeeping, meals, medical care, and other assistance is available to residents as needed.

assisted reproductive technology (ART) (plural: assisted reproductive technologies) Includes all fertility treatments in which both eggs and sperm are handled. In general, ART procedures involve surgically removing eggs from a woman's ovaries, combining them with sperm in the laboratory, and returning them to the woman's body or donating them to another woman.

assumption (plural: assumptions) A fact, statement, or premise that is considered true and that guides the underlying logic of a theory.

attachment The tendency to remain close to a familiar individual who is ready and willing to give care, comfort, and aid in time of need.

attachment behavior system A complex set of reflexes and signaling behaviors that inspire caregiving and protective responses in adults; these responses shape a baby's expectations and help create an image of the parent in the child's mind.

attachment scheme A set of internal mental representations that an infant has of the anticipated responses of a caregiver.

attention An infant's ability to focus on an object or task as well as to shift or redirect focus from one object to another.

attractiveness Having a pleasing or handsome appearance that may play a role in the arousal of romantic or sexual feelings.

auditory acuity The ability to recognize sounds of varying pitch and loudness.

autonomous morality A relatively mature moral perspective in which rules are viewed as a product of cooperative agreements.

autonomy The ability to behave independently, to do things on one's own.

autosomal Being or pertaining to a chromosome other than a sex chromosome.

avoidance conditioning A kind of learning in which specific stimuli are identified as painful or unpleasant and are therefore avoided.

avoidant attachment A form of insecure attachment in which infants avoid contact with their mothers during the reunion segment of the strange situations or ignore their mothers' efforts to interact. At home, these babies cry a lot, they are not readily soothed by contact with the caregiver, and yet they are quite distressed by separations.

babbling The vocal sounds of infants after about the sixth week that are initially characterized by sounds used in many languages and then begin to reflect the sounds and intonation infants are most likely to hear in their caregivers' speech.

behavioral inhibition A combination of fearfulness, a low threshold for arousal in the presence of novel or unusual stimuli, and general cautiousness.

behavioral slowing Age-related delay in the speed of response to stimuli.

bereavement The long-term process of adjustment to the death of a loved one that is more all-encompassing than grief and is commonly accompanied by physical symptoms, role loss, and a variety of intense emotions, including anger, sorrow, anxiety, and depression.

bias In research, a systematic error or distortion introduced by selecting or encouraging one outcome over others; a tendency to create conditions or interpret results in such a way as to confirm a previously held belief.

bidirectional In developmental systems theory, the back-and-forth regulation of the person and the environment over time.

bilingualism The ability to speak two languages fluently.

binge drinking Quickly consuming five or more drinks in a row.

biological system Includes all those processes necessary for the physical functioning of the organism. Sensory capacities, motor responses, and the workings of the respiratory, endocrine, and circulatory systems are all biological processes.

biopsychosocial Of or pertaining to the interaction among biological, social, and psychological factors.

birth culture A culture's beliefs, values, and guidelines for behavior regarding pregnancy and childbirth.

blended families A family that includes children from the previous marriage of one or both of the marital partners.

body dissatisfaction Body image disturbances; the state of feeling sad or angry at the way one's body looks.

boundaries In family systems theory, what determines who is considered to be a family member and who is an outsider. They influence the way information, support, and validation of the family unit are sought and the way new members are admitted into the family.

bulimia nervosa A habitual disturbance in eating behavior, mostly affecting young women of normal weight which is characterized by frequent episodes of grossly excessive food intake followed by self-induced vomiting to prevent weight gain.

cardiopulmonary death A set of criteria for death that includes lack of a heartbeat and lack of respiration.

care The commitment to be concerned.

career A period of time spent in a particular occupation or profession, often involving transitions, and a trajectory from one phase to another.

career choice A choice of occupation that will influence one's personal financial resources and opportunities.

career decision making A process which takes place at various points in one's occupational life that involves reviewing alternatives and assimilating factors such as social and historical contexts, socioeconomic factors, individual talents, identity development and experience into work-related decisions.

career decision-making self-efficacy The state of confidence about being able to accurately assess one's abilities, gather relevant information, formulate appropriate goals, make plans to achieve those goals, and solve the problems that pose barriers to the achievement of goals.

career indecision The inability to choose an occupation; common in later adolescence due to the complexity of the work world.

career maturity The stage at which a person has developed decision-making strategies and the self-insight that permit a realistic career choice.

career stagnation A lack of advancement or growth in one's occupational path; a sense of disillusion about the meaning or value of one's work.

caregiving The nurturing responses of the caregiver that form a corresponding behavioral system we often refer to as parenting.

caring Displaying kindness and concern for others.

caring orientation Moral decision making based on one's responsibility for others and feelings of connection to them.

case study An in-depth description of a single person, family, social group, or social setting.

categorical identification Self-understanding that relies on the categories one fits into, such as physical characteristics and religion.

categorization The process of arranging, classifying, or describing by labeling or naming.

causality The relation between a cause and an effect.

causal schemes The capacity to anticipate that certain actions will have specific consequences.

cell differentiation A process whereby cells take on specialized structures related to their function.

cell nucleus The part of the cell that contains the genetic material essential to reproduction and protein synthesis.

central process The dominant context or mechanism through which the psychosocial crisis is resolved.

cervix The narrow lower end of the uterus which forms the beginning of the birth canal.

cesarean section A procedure that removes a baby from its mother surgically through an incision in the uterine wall when a spontaneous vaginal delivery would be dangerous to the mother or the newborn.

childbearing Related to the process of having babies.

child care The wide diversity of arrangements that provide for the physical, emotional, social, nutritional and financial needs of children.

choice phase In Tiedeman's career decision model, the phase when the person decides which action alternative to follow. The decision is solidified in the person's mind as he or she elaborates the reasons why the decision is beneficial. There is a sense of relief and optimism as the person develops a commitment to executing the decision.

chromosomal disorders A disorder or birth defect that is linked to a specific chromosomal abnormality.

chromosome (plural: chromosomes) One of the rod-like bodies in a cell nucleus that contains genetic material and that divides when the cell divides. In humans, there are 23 pairs of chromosomes.

chronic illnesses Long-lasting, ongoing illnesses.

chronically depressed Experiencing depression over a long period of time.

clarification phase In Tiedeman's career decision model, the phase when the person more fully understands the consequences of his or her commitment to the decision that has been made. He or she plans definite steps to take and may actually take them or may delay them until a more appropriate time. The self-image is prepared to be modified by the decision.

classification The action of grouping objects according to some specific characteristics they have in common, including all objects that show the characteristic and none that do not.

climacteric The period of menopause for women and a parallel period of reduced reproductive competence for men.

clinical samples Populations who are or have been treated for a problem, or who are waiting to be treated.

clique (plural: cliques) A small friendship group of 5 to 10 people.

close friends People who play together, like the same activities, share common interests, enjoy each other's company, and count on each other for help.

code switching Switching from one language to another as the conversational situation demands.

codominance A condition in which both alleles of a specific gene contribute to the characteristic that is expressed, as in AB blood type.

coercive escalation A style of interaction in which the probability that a negative remark will be followed by another negative remark increases as the chain of communication gets longer and longer.

cognition The capacity for knowing, organizing perceptions, and problem solving.

cognitive competencies A person's knowledge, skills, and abilities.

cognitive functioning A very broad term that encompasses the range of cognitive abilities.

cognitive map An internal mental representation of the environment.

cognitive restructuring A process that helps people cope with social anxiety by identifying thoughts that increase their strong emotions such as anger, anxiety, or sadness, challenge the accuracy of those thoughts, and replace them with interpretations that are more realistic and less disruptive to adaptive behavior.

cognitive unconscious The range of mental structures and processes that operate outside awareness but play a significant role in conscious thought and action.

cohabitation Two or more people living together, with or without the intention of marriage.

cohort In research design, a group of individuals who are studied during the same time period. In life course analysis, a cohort is a group of people who are roughly the same age during a particular historical period.

cohort sequential design See cohort sequential study.

cohort sequential study A research design that combines cross-sectional and longitudinal methods. Cohorts consist of participants in a certain age group. Different cohorts are studied at different times. New cohorts of younger groups are added in successive data collections to replace those who have grown older. This design allows the analysis of age differences, changes over time, and the effects of social and historical factors.

collective efficacy A strong sense of social cohesion with a high level of informal social control in a community.

collectivism Worldview in which social behavior is guided largely by the shared goals of a family, tribe, work group, or other collective.

combinatorial skills The ability to perform mathematical operations, including addition, subtraction, and multiplication. These skills are acquired during the stage of concrete operational thought.

commitment Consists of a demonstration of personal involvement in the areas of occupational choice, religion, and political ideology.

common bond Interpersonal ties that provide feelings of acceptance and emotional support.

common identity Shared roles involving pressure to comply with group expectations.

communal norm A family science theory that suggests each person pays close attention to their partner's needs and acts in ways that will support the partner's welfare. In a communal relationship, each partner tries to meet the needs of the other within reason.

communication The act or process of using words, sounds, signs, or behaviors to express or exchange information or to express your ideas, thoughts, feelings, to someone else.

communication repairs Periods of recovery in normal mother–infant interactions that follow periods of mismatch so that infants and mothers cycle again through points of coordination in their interactions.

communicative competence The ability to use all the aspects of language in one's culture, such as systems of meaning, rules of sentence formation, and adjustments for the social setting.

communion The commitment to and consideration for the well-being of others.

community-based long-term health care A component of the Medicare program which provides medical and social services to those who are chronically ill and eligible for institutionalization but who, nevertheless, live in the community.

comparative assessments Self-understanding that relies on comparisons of oneself with social norms and standards or of oneself with specific other people.

competence The exercise of skill and intelligence in the completion of tasks; the sense that one is capable of exercising mastery over one's environment.

competence motivation The desire to exercise mastery by effectively manipulating objects or social interactions.

competition A contest between rivals.

complicated grief Persistent signs of bereavement that impair functioning including intense sorrow or inability to think about anything other than the loss after more than six months following the loss or death of a loved one.

compulsions Repetitive ritualized actions that serve as mechanisms for controlling anxiety.

compulsive sexual behavior A compulsive need to relieve anxiety through sex.

computational skills Comprehending and using numbers in the arithmetic processes of addition, subtraction, multiplication, and division.

concrete operational thought In Piaget's theory, a stage of cognitive development in which rules of logic can be applied to observable or manipulable physical relations.

confidence A conscious trust in oneself and in the meaningfulness of life.

confidential Private.

conflict of interest Something that may influence a researcher's judgment, such as when a researcher has a financial or personal investment in a study.

conformity Behavior, such as dress, talk, or jokes, that is the same as the behavior of most other people in a particular group.

congruence In a romantic or marital relationship, the state in which the partners are similar or agree in how they approach conflict.

conscientiousness A personality dimension associated with doing what is right and doing one's work or duty well.

conscious processes The mental capacities that contribute to awareness of one's immediate surroundings as well as one's thoughts, feelings, and actions. Conscious processes are under the control of the person.

conservation The concept that physical changes do not alter the mass, weight, number, or volume of matter. This concept is acquired during the concrete operational stage of cognitive development.

conservation of number Understanding that certain physical transformations will not alter the number of units in a set.

constructivist perspective The view that gender differences are a product of particular interactions that have a socially agreed-upon, gender-related meaning. In this view, the specific behaviors that are described as masculine or feminine depend largely on the situation, including expectations that people will behave in gender appropriate ways.

contactful A mode or style of interaction that is open to the other person's point of view and that also clearly expresses the speaker's own position.

contactful interactions Interactions that are open to the other's point of view and clearly express the speaker's point of view.

contexts of development The interrelated conditions in which development occurs. Family, culture, and ethnic group are three of the major contexts that have an effect on development. Work organizations, community settings, child care programs, schools, religious groups, community clubs, athletic teams, cities, counties, states, and nations may also have influence. Economic and historical factors such as war, political revolution, famine, or economic collapse are additional factors that have been shown to affect development.

contextual dissonance The difference between the characteristics of the primary childrearing and home environment and other environments in which the child participates.

contextualization of learning Offering instruction in ways that first draw of a child's existing experiences, knowledge, and concepts and then expand them in new directions.

continuing care retirement community A residential setting offering housing and medical, preventive health, and social services to residents who are well at the time they enter the community.

continuity A condition that characterizes a culture when a child is given information and responsibilities that apply directly to his or her adult behavior.

contraception Deliberate prevention of conception, impregnation, or the spread of disease through sexual behaviors.

control group The participants in an experiment who do not experience the manipulation or treatment and whose responses or reactions are compared with those of participants who are treated actively to determine the effects of the manipulation.

controlling interactions Interactions in which one person expresses his or her point of view and does not take the other person's point of view into consideration.

conventional level Stage II of Kohlberg's moral reasoning theory which reflects a concern about the maintenance of the existing rules and laws and a respect for legitimate authority.

conventional morality A stage of moral reasoning described by Kohlberg in which right and wrong are closely associated with the rules created by legitimate authorities, including parents, teachers, or political leaders.

cooperation Working or acting together for a common purpose or benefit.

coordination Refers to two related characteristics of interaction—matching and synchrony.

coparenting A respectful relationship in which parents who are not living together encourage active involvement with their children.

coping Active efforts to respond to stress. Coping includes gathering new information, maintaining control over one's emotions, and preserving freedom of movement.

core pathologies Destructive forces that result from severe, negative resolutions of the psychosocial crises.

correlation A measure of the strength and direction of the relationship among variables.

cosmic transcendence Feelings of cosmic communion with the spirit of the universe and a redefinition of time, space, life, and death.

couvade A ritual in which an expectant father takes to his bed and observes specific taboos during the period shortly before birth.

creativity The ability to abandon old forms or patterns of doing things and to think in new ways.

credibility The quality of being accepted as true, real, or honest; having acknowledged expertise in a field.

crisis A dramatic emotional or circumstantial upheaval in a person's life. In psychosocial theory, this often refers to a normal set of stresses and strains rather than to an extraordinary set of events, and it consists of a period of role experimentation and active decision making among alternative choices.

critical period A time of maximum sensitivity to or readiness for the development of a particular skill or behavior pattern.

cross-sectional study (plural: cross-sectional studies) A research design in which the behavior of individuals of different ages, social backgrounds, or environmental settings is measured once to acquire information about the effects of these differences.

crowd (plural: crowds) A large group that is usually recognized by a few predominant characteristics, such as the "preppies," the "jocks," or the "druggies."

crystallization phase In Tiedeman's career decision model, the phase when the person becomes more aware of the alternatives for action and their consequences. Conflicts among alternatives are recognized, and some alternatives are discarded. The person develops a strategy for making the decision, in part by weighing the costs and benefits of each alternative.

crystallized intelligence (Gc) Skills and information that are acquired through education and socialization.

cultural determinism The theoretical concept that culture shapes individual experience.

cultural pathways Adults in each culture have values and goals for themselves and for their children that shape and organize the socialization process and activities of daily life.

cultural relativism Morality is viewed as a system of rules that are agreed upon in order to preserve human rights and social order. These rules are understood as having been created in cultural and historical contexts, and can be altered as the norms of the community change.

cultural tools Symbol systems such as language of one's society that permit individuals to alter their environments and guide, regulate, and redefine themselves.

culture Refers to the socially standardized ways of thinking, feeling, and acting that are shared by members of a society.

culture carriers People, such as parents, teachers, religious leaders, and elders, who use strategies to transmit critical practices and values.

cumulative relation In heredity, when the allelic states of a gene in a single pair of chromosomes combine to influence a trait.

cyberbullying The use of electronic media to send threatening, intimidating, or humiliating messages.

death anxiety Personal fear and worry about death.

decentering Gaining some objectivity over one's own point of view; reducing the dominance of one's subjective perspective in the interpretation of events.

defense mechanism A technique, usually unconscious, that attempts to alleviate the anxiety caused by the conflicting desires of the id and the superego in relation to impulses (e.g., repression, denial, projection).

degree of suffering Amount or intensity of pain and other symptoms, including shortness of breath, inability to eat, and limited mobility, that a person experiences at the end of life.

delay of gratification The exertion of willpower in order to resist the strong immediate pull or temptation of something desirable.

delinquency Crimes for which an adult could be prosecuted when committed by an adolescent, and status offenses which are illegal for adolescents, such as underage drinking.

demand-withdrawal pattern A pattern of communication in which one member of a marital relationship (the demander) nags, criticizes, and makes demands of the other to change, while the partner (the withdrawer) avoids confrontation, becomes silent, and withdraws.

dementia Deterioration of intellectual faculties, such as memory, concentration, and judgment, sometimes accompanied by emotional disturbance and personality changes. Dementia is caused by organic damage to the brain (as in Alzheimer's disease), head trauma, metabolic disorders, or the presence of a tumor.

dependency In the study of aging, an assessment of difficulties in the activities of daily living usually required to function independently. Beyond very basic types of self-care, an expanded notion of dependency refers to difficulties in managing instrumental activities of daily living.

dependent variable A factor that is defined by a participants responses or reactions and that may or may not be affected by the experimenter's manipulation of the independent variable.

depressed mood Refers to feelings of sadness, a loss of hope, a sense of being overwhelmed by the demands of the world, and general unhappiness.

depression A state of feeling sad, often accompanied by feelings of low personal worth and withdrawal from relations with others.

depressive syndrome This term refers to a constellation of behaviors and emotions that occur together. The syndrome usually includes complaints about feeling depressed, anxious, fearful, worried, guilty, and worthless.

deselection The process in which an adolescent begins to differ from his or her friends on important behaviors or values, which usually causes the relationship to drift apart.

despair Feeling a loss of all hope and confidence.

developmental change Patterns of growth and reorganization.

developmental stage A period of life dominated by a particular quality of thinking or a particular mode of social relationships. The notion of stages suggests qualitative changes in competence at each phase of development.

developmental systems theory This perspective emphasizes the ongoing interaction and integration across many levels of the human organism from the genetic to the behavioral level, within the nested contexts of the person, family, community, and culture, to consider both continuity and change over individual and historical time.

developmental task A set of skills or competencies acquired at a specific stage of development.

developmental viability A point at which a fetus may survive outside the uterus.

differentiation The extent to which a social system encourages closeness while supporting the expression of differences.

diffidence The inability to act due to overwhelming self-doubt.

dilation In childbirth, the gradual enlargement of the woman's cervix.

disability An umbrella term that includes a wide variety of possible functional challenges.

disclosure Sharing personal information with others.

discontinuity A condition that characterizes a culture when a child is either barred from activities that are open only to adults or forced to unlearn information or behaviors that are accepted in children but considered inappropriate for adults.

disdain A feeling of scorn for the weakness and frailty of oneself or others.

disengaged relationships Infrequent contact and a sense that the members of the family do not really seem to care about one another.

disequilibrium In Piaget's theory, a condition when changes in the organism or changes in the environment require a revision of schemes or mental structures.

dismissing avoidant attachment An attachment outcome in which people have a positive model of the self and a negative model of others.

disorganized attachment Babies' responses are particularly notable in the reunion sequence. In the other three attachment patterns, infants appear to use a coherent strategy for managing the stress of the situation. The disorganized babies have no consistent strategy: They behave in contradictory, unpredictable ways that seem to convey feelings of extreme fear or utter confusion.

dissociation A sense of separateness or withdrawal from others; an inability to experience the bond of mutual commitment.

divorce The legal dissolution of a marriage.

division of labor Splitting the activities needed to accomplish a task between participants.

dizygotic twins Twins developed from two separate fertilized ova; also called fraternal twins.

dominance If one allele is present, its characteristic is always observed, whether the other allele of the allelic pair is the same or not.

doubt A sense of uncertainty about one's abilities and one's worth.

Down syndrome A chromosomal irregularity in which the child has an extra chromosome 21. The condition results in mental retardation.

drives In psychosexual theory, sexual and aggressive forces that have a biological or somatic origin. They are a result of some metabolic functions but are also intimately linked to psychological processes.

dropping out of college Leaving a college or university in which one is enrolled before completing a degree.

dual-earner marriages A marriage in which both partners earn income for the household.

durable power of attorney A document that authorizes someone to act on behalf of a person in financial and property matters and health care decisions that can go into effect either when the agreement is signed or when a disability occurs.

dying trajectory The time during which a person goes from good health to death.

dyslexia A learning disability involving difficulties in reading, spelling, and writing.

eating disorders Any of several psychological disorders such as anorexia nervosa and bulimia characterized by disturbances in the daily consumption of food, preoccupation with thinness, or binge and purge behaviors.

ecological niche The place where an organism lives and the role it plays in the ecosystem.

ecological validity The applicability of a controlled laboratory situation in the real world.

education In the broadest sense, a culture's process for transmitting valued knowledge and skills from one generation to the next.

effacement The shortening of the cervical canal preceding childbirth.

efficacy The capacity for producing a desired result, including planning intentional actions, guiding and directing one's own behaviors toward a goal, and reflecting on ones actions to assess their quality, impact, and purpose.

effortful control A child's ability to suppress a dominant response and perform a subdominant response instead.

ego In psychosexual theory, the mental structure that experiences and interprets reality. The ego includes most cognitive capacities, including perception, memory, reasoning, and problem solving.

egocentric empathy When one recognizes distress in another person and responds to it in the same way one would respond if the distress were one's own.

egocentric speech In Piaget's observation, toddlers use this to control and direct their behavior. The speech is considered egocentric because it is not intended to communicate with anyone else and often doesn't make sense to anyone else. Vygotsky suggested that egocentric speech is a component of the problem-solving function.

egocentrism The perception of oneself at the center of the world; the view that others and events base their behavior on or occur as a result of one's own perceptions.

ego ideal A set of positive standards, ideals, and ambitions that represent the way a person would like to be.

ego psychology The study of the development and differentiation of the ego as integrative, adaptive, and goal directed.

Electra complex In psychosexual theory, a conflict that results from ambivalence surrounding heightened sexuality during the phallic stage. The daughter has a strong, sexualized attraction to her father, and her mother becomes a fantasized rival. See Oedipal complex for boys.

electronic fetal heart rate monitoring The continuous monitoring of fetal heart rate using an electronic amplification device.

embryo The developing human individual from the time of implantation to the end of the eighth week after conception.

embryonic period A stage of pregnancy in the first trimester that occur after the germinal period, and is devoted primarily to elaboration of the supportive elements that will house the embryo. The embryonic period lasts about 10 weeks after the last menstrual period.

emotional regulation Strategies for coping with intense emotions, both positive and negative. Caregiver behavior and observation are important factors in the development of emotional regulation.

empathy The capacity to recognize and experience the emotional state of another person.

empathy for another's feelings When one shows empathy for a wide range of feelings and anticipates the kinds of reactions that might really comfort someone else.

empathy for another's life conditions When one experiences empathy in understanding the life conditions or personal circumstances of a person or group.

empowerment Sharing information and authority so that people can take initiative and make decisions to solve problems; a concept applied in any context where power is typically unequal, such as parent–child , doctor–patient, or supervisor–subordinate.

enactive attainment (plural: enactive attainments) Personal experience of mastery.

encoding (plural: encodings) In cognitive behaviorism, the construct that a person has about the self, the situation, and others in the situation.

enculturation The process by which culture carriers teach, model, reward, punish, and use other symbolic strategies to transmit critical practices and values.

endogamy Marriage within one's well-defined group, such as one's ethnic or religious group.

enmeshed relationships Characterized by over involvement in one another to the extent that any change in one family member is met by strong resistance by the others; individuality is viewed as a threat to the relationship.

environmental toxins Poisonous substances in a pregnant woman's environment that may cause malformations to the fetus she carries, such as lead, mold, and chemicals in plastics and pesticides.

enzymes Complex proteins produced by living cells that act as catalysts for biochemical reactions.

epigenetic marks Chemicals that sit on top of the genes and instruct them to switch on or off.

epigenetic principle A biological plan for growth such that each function emerges in a systematic sequence until the fully functioning organism has developed.

epigenetics Activities at the biochemical level that alter gene expression but do not alter the genome itself.

episodic memory Recall of situations and data.

equilibration Efforts to reconcile new perspectives and ideas about basic moral concepts, such as justice, intentionality, and social responsibility with one's existing views about what is right and wrong when a stage change occurs.

equilibrium In Piaget's theory, the balance that every organism strives to attain in which organized structures (sensory, motor, or cognitive) provide effective ways of interacting with the environment.

estrogen (plural: estrogens) The major female sex hormone.

ethical principles Standards of right and wrong, especially as they govern areas of moral and professional responsibility.

ethics Principles of conduct founded on a society's moral code.

ethnic group (plural: ethnic groups) A group of people who share a common cultural ancestry, language, or religion within a larger cultural context.

ethnic group identity Knowing that one is a member of a certain ethnic group; recognizing that aspects of one's thoughts, feelings, and actions are influenced by ones ethnic membership; and taking the ethnic group's values, outlook, and goals into account when making life choices.

ethnic identity An aspect of self-concept related to one's sense of belonging and connection to one or more ethnic groups.

ethnography A type of observation in which behavior in a setting is carefully observed and recorded without any other kind of manipulation; often used to describe complex cultural activities.

ethology The comparative investigation of the biological basis of behavior from an evolutionary perspective to determine the proximal causes of behavioral acts, the relative contribution of inheritance and learning to these acts, and the adaptive significance and evolutionary history of different patterns of behavior within and across species.

euthanasia The practice of ending someone's life for reasons of mercy.

evaluation A judgment of the accuracy and/or usefulness of research findings, and their implications for the confirmation or revision of theory.

evolutionary psychology The study of the long-term, historical origins of behavior.

exchange norm A family science theory that suggests each person expects to satisfy the needs of the partner and to have needs met in about the same amount. It includes a sense of obligation so that what one receives from the partner should be returned in similar value.

exclusivity A shutting out of others for elitist reasons.

executive functioning (noun: executive functions) Includes several cognitive capacities, including the ability to reject irrelevant information, formulate complex hypothetical arguments, organize an approach to a complex task, and follow a sequence of steps to task completion. Often associated with advances in the development of the prefrontal cortex.

exosystem One or more settings that do not involve the developing person as an active participant but in which events occur that affect or are affected by what happens in the setting containing the developing person.

expansion Elaborating on a child's expression by adding more words.

expectancies Expectations about one's ability to perform, the consequences of one's behavior, and the meaning of events in one's environment.

expectations Views held by oneself or by others about what would be appropriate behavior in a given situation or at a given stage of development.

experiential transcendence A way of experiencing immortality through achieving a sense of continuous presence.

experiment A research method best suited for examining causal relationships in which some variable or group of variables is systematically manipulated to examine its effect on an outcome.

experimental group The participants who experience the manipulation or treatment in an experiment.

expert A person who has become proficient at a skill due to a combination of aptitude, training, and practice. The final stage of a developmental progression to acquire a skill.

expertise A quality of individuals who focus their intelligence on intensive study, training, and repeated opportunities for problem solving within a domain in which they become specialists.

exploration phase In Tiedeman's career decision model, the phase when a person realizes that a career decision must be made and therefore begins to learn more about those aspects of the self and the occupational world that are relevant to the impending decision. The person begins to generate alternatives for action. Uncertainty about the future and the many alternatives is accompanied by feelings of anxiety.

external frames of reference When a child evaluates his or her own performance in light of parent, teacher, or peer feedback and observations of the performance of other children in the class.

externalizing problems Having the inability to suppress impulses. Intense anger in conditions of frustration, an inability to delay gratification, and lack of empathy are experienced. Anger and frustration are directed outward to other people or objects.

external validity The degree to which the results of an experiment are applicable to situations beyond the experiment itself.

extinction (1) In psychosocial theory, the negative pole of the psychosocial crisis of elderhood, in which it is feared that the end of one's life is the end of all continuity. (2) In evolutionary theory, the failure of a species to adapt to changing environmental conditions results in a gradual process in which the species no longer exists.

extroversion Personality dimension that includes such qualities as sociability, vigor, sensation seeking, and positive emotions.

faceness The properties of appearing like a human face. Infants seem to have a special visual category for the properties of a human face, showing surprise when facial features are disorganized or upside down.

fallopian tube The tube, extending from the uterus to the ovary, in which fertilization takes place.

family Two or more individuals living together who are related by birth, marriage, partnership agreement, or adoption.

family constellation The many variables that describe a family group, including the presence or absence of mother and father; the number, spacing, and sex of siblings; and the presence or absence of extended family members in the household.

family of origin The family into which one is born.

family of procreation The family one begins as an adult.

fast–mapping (verb: fast-map) Forming a rapid, initial, partial understanding of the meaning of a word by relating it to the known vocabulary and restructuring the known-word storage space and its related conceptual categories.

fearful avoidant attachment An attachment outcome in which people have a negative model of both self and others.

feedback The process by which a system, often biological or ecological, is modulated, controlled, or changed by the product, output, or response it produces.

feedback loop (plural: feedback loops) The section of a control system that allows for feedback and self-correction and that adjusts its operation according to differences between the actual output and the desired output.

feedback mechanisms In systems theory, the operations in an open system that produce adaptive self-regulation by identifying and responding to changes in the environment.

femininity Gender traits associated with being expressive and communal (e.g., valuing interpersonal and spiritual development, and being tender, sympathetic, and concerned about the well-being of others).

fertility rate The average number of births per woman of childbearing age.

fertilization The penetration of an egg by a sperm.

fetal alcohol spectrum disorders An umbrella term for the range of effects that can occur in an individual whose mother drank alcohol during pregnancy. These effects include physical, mental, behavioral, and learning disabilities with possible lifelong implications.

fetal alcohol syndrome A condition of the fetus involving central nervous system disorders, growth deficiency, low birth weight, and malformations of the skull and face; the condition is associated with use of alcohol by mothers during pregnancy.

fetal period A stage of pregnancy beginning in the first trimester after the embryonic period. During this period the fetus continues to grow and the sex organs form. The fetus's heartbeat can be heard with an amplified stethoscope, called a Doppler. This period lasts until birth.

fetal viability The maturational age at which the fetus can survive outside the uterus.

fetoscopy Examination of the fetus through the use of a fiber-optic lens.

fetus The unborn infant. Usually, the term fetus refers to infants between 8 weeks of gestational age and birth. See embryo.

fidelity (to others) The ability to freely pledge and sustain loyalties to others; the ability to freely pledge and sustain loyalties to values and ideologies.

filial obligation The responsibilities of adult children for their aging parents.

first word The first words a baby uses, typically between the ages of 12 and 18 months. Most first words have a shared meaning between the baby and the caregiver.

fitness (1) The genetic contribution of an individual to the next generation's gene pool relative to the average for the population, usually measured by the number of that individual's offspring or close kin that survive to reproductive age. (2) Patterns of activity or inactivity, endurance or frailty, and illness or health that influence the ability to manage tasks of independent daily living.

fixation In psychosexual theory, the continued use of pleasure-seeking or anxiety-reducing behaviors appropriate to an earlier stage of development.

fluid intelligence (Gf) The ability to impose organization on information and to generate new hypotheses.

foreclosure See identity foreclosure.

formal operational thought In Piaget's theory, the final stage of cognitive development, characterized by reasoning, hypothesis generation, and hypothesis testing.

formal operations Complex cognitive capacities, such as reasoning, hypothesis generation, and hypothesis testing.

foundational category In cognitive development, a fundamental mental classification, such as the distinction between human beings and inanimate objects.

frailty Physical weakness or disease, often stemming from old age, that prevents individuals from performing activities of daily living.

fraternal twins Children born at the same time who developed from two different ova.

friendship (plural: friendships) The relationship between people who are attached to one another by affection, esteem, shared interests, etc.

functional independence Requiring little or no help with the activities of daily living.

fulfillment theories Theories that emphasizes the purposive, goal-oriented strivings that characterize adult life, particularly those strivings for personal fulfilment and self-actualization.

gamete (plural: gametes) A mature germ cell involved in reproduction; a sperm or an ovum.

gender Refers to the integrated cognitive, social, and emotional schemes associated with being male or female.

gender constancy When children learn the biological basis of gender and that one's gender does not change.

gender contentedness A feeling of satisfaction with one's biological sex and related gender expectations.

gender dysphoria A condition in which one has a strong aversion to some or all of the physical characteristics or social roles associated with one's biological sex.

gender gap Systematic differences between men and women in some measurable variable such as income, length of life, or elected representation in government.

gender identification Incorporation into one's self-concept of the valued characteristics of male or female that become integrated into an early scheme for thinking of oneself as either male or female.

gender identity A set of beliefs, attitudes, and values about oneself as a man or woman in many areas of social life, including intimate relations, family, work, community, and religion.

gender label (plural: gender labels) The word boy or girl. First component of gender identity, in which children learn to refer to themselves as a boy or girl and to identify other children by applying the word correctly.

gender permanence An appreciation that a boy grows up to be a man and a girl grows up to be a woman. One's sex is permanent over time, even though many things about one might change.

gender-role convergence A transformation in which men and women become more androgynous and more similar in gender orientation during later life.

gender-role expectations The cultural and subcultural expectations concerning the appropriate behavior of male and female individuals.

gender-role standards Attributes held by the culture for males and females. These attributes can include both precepts and sanctions.

gender scheme (plural: gender schemes) A personal theory about cultural expectations and stereotypes related to gender.

gene (plural: genes) The fundamental physical unit of heredity. A gene is a linear sequence of nucleotides along a segment of DNA that carries the coded instructions for the synthesis of RNA, which, when translated into protein, leads to hereditary characteristics.

gene pool The genetic information contained in the genes of the population or culture that provides the ancestry for an individual.

generalizability The extent to which we can say with confidence that the observations made for a sample would apply to other groups.

generativity The capacity to contribute to the quality of life for future generations. A sense of generativity is attained toward the end of middle adulthood.

genetic anomalies Neurological or physical abnormalities that have a genetic cause.

genetic counseling Recent discoveries make it possible to identify the genes responsible for certain forms of disease and genetic anomalies. Couples who have reason to believe that they may carry genes for one of these disorders can be tested and advised about the probability of having children who may be afflicted.

genital basis of gender labels An understanding that a person's genitals provide the physical basis for distinguishing male and female gender roles.

genital stage In psychosexual theory, a period in which a person finds ways of satisfying sexual impulses in mature, dyadic relationships, typically beginning with the onset of puberty.

genome The full set of chromosomes that carries all the inheritable traits of an organism.

genotype The hereditary information contained in the cells of an individual. Genotype may or may not be observable in the phenotype. See phenotype.

gentrification A pattern of real estate change in which a higher income group buys property and develops residential and commercial projects in an area that has previously been serving a lower income group.

germinal period A stage of pregnancy in the first trimester that occur immediately after fertilization and lasts until implantation, typically six days after fertilization. During this stage, the egg begins to divide and is referred to as a zygote. After implantation, the zygote is called an embryo and the pregnancy enters the embryonic period.

gestation The period from conception to birth.

gestational age The age of the fetus from the time of conception until birth.

Glick effect Statistical evidence of a lack of persistence that relates dropping out of high school or college with a high probability of divorce.

global empathy Distress experienced and expressed as a result of witnessing someone else in distress.

globalization A process that includes the rapid spread of materials and products, ideas, images, capital flows, and people across spaces and borders (national or otherwise) that formerly were far more difficult if not impossible to connect.

goal (plural: goals) The result or achievement toward which effort is directed.

goal-corrected partnership In Bowlby's attachment theory, the capacity that emerges in toddlerhood and early school age in which children begin to find more flexible and adaptive ways to maintain proximity with the object of attachment and to seek reassurance under stressful situations. As a result, children are able to manage negotiated separations more easily.

goal domains Areas of life that are viewed as important and that contribute to life satisfaction such as job or daily activities, social contact and family, health, income, self-reliance, leisure time, and physical activity.

goal orientation Guiding direction of one's life goals, especially the distinction between agentic (such as focusing on achievement, power, and the expression of personal abilities) and communal (focusing on intimacy, affiliation, and contributions to the welfare of others).

goal-related activities The actions one takes to achieve one's life goals.

good death The ideal conditions a person envisions surrounding death and dying.

grammar Rules for the arrangement of words and phrases in a sentence and for the inflections that convey gender, tense, and number.

grandparenthood The stage of life one enters when one's first grandchild is born.

gray matter The cell body of neurons and the nonmyelinated sections of axons and dendrites.

grief The cognitive and emotional reactions that follow the death of a loved one.

grief work A person's psychological efforts to work through the reality of loss of a loved one and the feelings in which the person must (1) achieve freedom from feelings of guilt about ways he or she had criticized or even harmed the person who died and feelings of regret for things left unsaid or undone; (2) make an adjustment to all the aspects of the environment from which the deceased is missing; and (3) begin to form new relationships.

group games Games that are more structured and somewhat more oriented to reality than play that is based primarily on imagination. These games combine fantasy with an emphasis on peer cooperation and competition.

group identity The positive pole of the psychosocial crisis of early adolescence, in which the person finds membership in and value convergence with a peer group.

group norms Collective expectations or rules for behavior held by members of a particular group.

guilt An emotion associated with doing something wrong or the anticipation of doing something wrong.

habituation A form of adaptation in which the child no longer responds to a stimulus that has been repeatedly presented.

harsh discipline A form of discipline that includes physical punishment, yelling, angry and prolonged timeouts, and threatening violence.

health literacy Knowing where to find trustworthy information about health concerns, understanding the information that is provided, and using the information to make informed decisions about one's health.

heteronomous morality A child's moral perspective, in which rules are viewed as fixed and unchangeable.

heterozygous Characterized by the presence of different alleles of a particular gene at the same locus.

higher mental processes In Vygotsky's theory, processes, particularly language and meaning, that emerge from a child's ongoing interactions within social, historical, and cultural contexts, as well as from the child's biological maturation.

holophrase (plural: holophrases) A single word functioning as a phrase or sentence.

homeostasis A relatively stable state of equilibrium.

homogamy When people are attracted to others who share important areas of similarity.

homozygous Characterized by the presence of two matched alleles of a particular gene at the same locus.

hope An enduring belief that one can attain one's essential wishes.

horizontal control system The flow of information between the right and left hemispheres of the brain.

hormones A group of chemicals, each of which is released into the bloodstream by a particular gland or tissue and has a specific effect on tissues elsewhere in the body.

hospice care An integrated system of medicine, nursing, counseling, and spiritual care for the terminally ill and their family that emphasizes pain control and emotional support and typically refrains from extraordinary measures to prolong life.

household All persons who occupy a housing unit, including both related family members and all unrelated persons.

housing options Alternative living arrangements including single-family homes, apartments, continuing care facilities, and nursing homes.

hyperarousal A response to exposure to violence and trauma, including low threshold for startle response, increases in heart rate, sleep disturbance, anxiety, and motor hyperactivity.

hypervigilance An increased arousal for threat-related stimuli, often as a result of experiencing trauma.

hypoactive sexual desire A decrease or absence of interest in sexual activity.

hypothesis A tentative proposition that can provide a basis for further inquiry.

hypothetico deductive reasoning A method of reasoning in which a hypothetical model based on observations is first proposed and then tested by deducing consequences from the model.

id In psychoanalytic theory, the mental structure that expresses impulses and wishes. Much of the content of the id is unconscious.

identical twins Children born at the same time who developed from the same ovum.

identification The process through which one person incorporates the values and beliefs of a valued other such as a parent.

identity achievement Individual identity status in which, after a crisis, a sense of commitment to family, work, political, and religious values is established.

identity confusion The negative pole of the psychosocial crisis of later adolescence in which a person is unable to integrate various roles or make commitments.

identity foreclosure Individual identity status in which a commitment to family, work, politics, and religious values is established prematurely without crisis.

identity process A process in which the older adolescent examines alternatives, selects goals in various domains (personal, occupational, financial cultural), makes personal and interpersonal commitments to achieve these goals, and takes the active steps to achieve them.

identity status One of four levels in the identity process characterized by different degrees of crisis and commitment.

illusion of competence An overestimation of one's abilities despite poor academic achievement or test performance.

illusion of incompetence Expressed by children who perform well in academic achievement tests yet perceive themselves as below average in academic ability and behave in accordance with this perception.

imaginary audience The preoccupation with what you believe other people are thinking about you.

imaginary companion (plural: imaginary companions) A make-believe friend, which may be an animal, a child, or some other creature, that springs complete in concept from the mind of a child. It is thought to occupy space. It has its own personality, which is consistent from day to day. It has its own likes and dislikes, which are not necessarily the same as those of its creator.

imitation Repetition of another person's words, gestures, or behaviors.

immortality The positive pole of the psychosocial crisis of very old age, in which the person transcends death through a sense of symbolic continuity.

impulse control The ability to delay gratification and to suppress a dominant response in order to perform a subdominant response.

inclusion In a school environment, the process of promoting contact between students with and without disabilities and creating an accepting social climate among students.

inclusive fitness The fitness of an individual organism as measured by the survival and reproductive success of its kin, each relative being valued according to the probability of shared genetic information, with an offspring or sibling having a value of 50 percent and a first cousin having a value of 25 percent.

independent variable The factor that is manipulated in an experiment, and the measured effects of the manipulation.

individual differences perspective The view that gender differences exist within the individual as persistent, internal attributes and that differences between boys and girls are stable characteristics that individuals bring to various situations.

individual identity The commitment to a personal integration of values, goals, and abilities that occurs as personal choices are made in response to anticipated or actual environmental demands at the end of adolescence.

individualism Worldview in which social behavior is guided largely by personal goals, ambitions, and pleasures.

induction (1) A form of discipline that points out the consequences of a child's actions for others. (2) In cognitive development, the realization that whatever holds true for one member of a category is likely to hold true for other members as well.

induction phase In Tiedeman's career decision model, the phase when a person encounters the new work environment for the first time. He or she wants to be accepted and looks to others for cues about how to behave. The person identifies with the new group and seeks recognition for his or her unique characteristics. Gradually, the self-image is modified as the person begins to believe in the values and goals of the work group.

industry A sense of pride and pleasure in acquiring culturally valued competences. The sense of industry is usually acquired by the end of the middle childhood years.

inertia A paralysis of thought and action that prevents productive work.

infant mortality rate The number of infants who die during the first year of life per 1,000 live births during that year.

infertility Inability to conceive or carry a fetus through the gestational period.

influence phase In Tiedeman's career decision model, the phase when the person is very much involved with the new group. He or she becomes more assertive in asking that the group perform better. The person also tries to influence the group to accommodate some of his or her values. The self is strongly committed to group goals. During this phase, the group's values and goals may be modified to include the orientation of the new member.

informants Participants in a researcher's study who will provide their insight, experience, and knowledge.

informed consent Telling all participants in a research study all aspects of the research that may influence their decision to participate.

in-group A group of which one is a member; contrasted with out-group.

in-group bias The tendency for members of a group to behave in ways that are more acceptable to other in-group members and to view members of the in-group more positively than people who are not members of the in-group.

inhibition A psychological restraint that prevents freedom of thought, expression, and activity.

initiative The ability to offer new solutions, to begin new projects, or to seek new social encounters; active investigation of the environment.

inner speech Language spoken softly or even silently to the self which guides behavior. In Vygotsky's theory, the internalization of social language is a transition between spoken language and thought.

institutional review A process in which representatives of an organization read and react to research proposals, applying guidelines for the ethical conduct of research and approving, modifying, or rejecting proposals based on these guidelines.

instrumental activities of daily living (IADLs) Basic tasks that are essential to maintaining one's daily life without dependence on informal or formal community support services.

instrumental reminiscence Reminiscence that emphasizes past accomplishments, past efforts to overcome difficulties, and the use of past experiences to approach current difficulties.

instrumental support Direct assistance, including help with chores, medical care, or transportation.

instrumental values The values placed on doing things that are challenging, reflected in the amount of time spent on and the degree of satisfaction achieved in such actions.

integration phase In Tiedeman's career decision model, the phase when group members react against the new member's attempts to influence them. The new member then compromises. In the process, he or she attains a more objective understanding of the self and the group. A true collaboration between the new member and the group is achieved. The new member feels satisfied and is evaluated as successful by the self and others.

integrative reminiscence Reminiscence that involves reviewing one's past in order to find meaning or to reconcile one's current and prior feelings about certain life events.

integrity The ability to accept the facts of one's life and to face death without great fear. The sense of integrity is usually acquired toward the end of later adulthood.

intellectual flexibility A person's ability to handle conflicting information, to take several perspectives on a problem, and to reflect on personal values in solving ethical problems.

intellectual vigor A person's ability to maintain and successfully utilize cognitive abilities.

interdependence A condition in which systems depend on each other, or in which all the elements in a system rely on one another for their continued growth.

intergenerational solidarity The closeness and commitment within parent–child and grandparent–grandchild relationships.

intermental In Vygotsky's theory, understanding or shared meaning between two or more people.

internal frames of reference When a child compares how well he or she can perform in one domain versus another.

internalization A process in which the values, beliefs, and norms of the culture become the values, beliefs, and norms of the individual.

internalized morality The ability to see oneself as a moral being whose actions have implications for the well-being of others; using closely held standards to judge their own behavior and the behavior of others.

internalizing problems Having overcontrol, intense worries and fears, and suppression of emotions. Anxiety is focused inward on the self.

internal validity The sample and methods are appropriate in an experiment.

interobserver reliability Two or more observers' codings of the same situation are compared to determine whether different observers rated the same event in the same way.

interpersonal interactions The frequency and quality of communication and time shared in a relationship.

interpersonal skills Skills that promote relationships and include at least three components: self-presentation, social scanning, and social flexibility.

interpretation The result of explaining or understanding something.

intersubjectivity A shared repertoire of emotions that enables infants and their caregivers to understand each other and create shared meanings. They can engage in reciprocal, rhythmic interactions, appreciate state changes in one another, and modify their actions in response to emotional information about one another.

interview A conversation used to discover people's opinions or experiences; information can be gathered in face-to-face encounters, via telephone, or other media.

intimacy The ability to experience an open, supportive, tender relationship with another person without fear of losing one's own identity in the process of growing close. The sense of intimacy is usually acquired toward the end of early adulthood.

intimate relationship (plural: intimate relationships) An open, supportive, tender relationship with another person without fear of losing one's own identity in the process.

intramental In Vygotsky's theory, an understanding of the special relationship between the desired goal and the communication required to achieve that goal.

introjection An unconscious psychic process by which a person incorporates the characteristics of another person into his or her own personality.

introspection Deliberate self-evaluation and examination of private thoughts and feelings.

in vitro fertilization A process where eggs are removed from the ovary and placed in a petri dish inside an incubator. A few drops of sperm are then added to the dish. If the eggs are fertilized and the cells begin to divide, they are implanted in the uterus for subsequent development.

iron deficiency anemia A nutrient disorder where there is not enough iron available for proper brain development. Babies who have severe iron deficiencies test lower in motor and cognitive development and show evidence of fearfulness, fatigue, and wariness.

isolation A crisis resolution in which situational factors or a fragile sense of self lead a person to remain psychologically distant from others; the state of being alone.

joblessness The state of not having work.

justice orientation Moral decision making based on human rights, respect for others, and fairness.

labor In pregnancy, involuntary contractions of the uterine muscles that occur prior to giving birth.

lack of congruence In a romantic or marital relationship, the state in which the partners are dissimilar or disagree in how they approach conflict.

language environment The sounds, system of meanings, rules for word and sentence formation, and guidelines for communication in social settings of a particular language. This includes the nature of language partners and language stimulation such as television, books, and other media.

language perception The ability to recognize sounds and differentiate among sound combinations before the meanings of these sounds are understood.

language production The generation of language material by an individual. One of the first significant events is the naming of objects.

latency In psychosexual theory, a period of development that occurs after the Oedipal or Electra conflict is resolved and lasts from about 7 years until puberty. No new significant conflicts or impulses arise. The primary personality development during this period is the maturation of the ego.

launching period The time in family life during which children leave home.

leadership A relationship between people; the process of helping a group shape a vision of its purpose and goals and of getting people, both inside and outside the group, to commit and recommit themselves to accomplishing that vision.

learned helplessness A belief that one's efforts have little to do with success or failure and that the outcome of task situations is largely outside one's control.

learning Any relatively permanent change in thought or behavior that is the consequence of experience.

legacy A bequest; something handed down from one generation to the next.

life course Reference to the integration and sequencing of phases of work and family life.

life expectancy The average number of years from birth to death, as based on statistical analyses of the length of life for people born in a particular period.

life satisfaction A sense of well-being based on an evaluation of one's progress toward achieving important life goals.

life span Refers to the typical length of time that any particular organism can be expected to live.

life structure One's living arrangement and social relationships that support one's physical and mental health.

lifestyle A relatively permanent structure of activity and experience, including the tempo of activity, the balance between work and leisure, and patterns of family and social relationships.

literacy The ability to read and write.

living arrangements The type of household or facility in which someone lives and the people an individual choose to live with.

living will A document instructing physicians, relatives, or others to refrain from the use of extraordinary measures, such as life support equipment, to prolong one's life in the event of a terminal illness.

locomotion The ability to move from one place to another.

loneliness The state of feeling sad because one is apart from other people, rejected by others, or because one has fewer social interactions than are desired.

longevity The length or duration of life.

longitudinal study A research design in which repeated observations of the same participants are made at different times in order to examine change over time.

long-term memory A complex network of information, concepts, and schemes related by associations, knowledge, and use. It is the storehouse of a lifetime of information.

loss-oriented coping Confronting one's pain, sadness, and the loss of a loved one and finding a place for the deceased in one's thoughts and memories in order to achieve emotional health and cognitive functioning.

love A profoundly tender affection for another person. Characterized by intimacy, passion and commitment.

love withdrawal A form of discipline in which parents express disappointment or disapproval and become emotionally cold or distant.

low-birth-weight babies Infants who weigh less than 2,500 grams (about 5 pounds, 8 ounces) at birth. This may be a result of being born before the full period of gestation, or it may result from the mother's inadequate diet, smoking, or use of drugs.

lower mental processes In Vygotsky's theory, natural processes that can be observed in animal behavior and in the problem-solving behaviors of infants and very young children.

macrosystem Refers to consistencies in the form and content of lower order systems (micro-, meso-, and exosystems) that exist or could exist at the level of the subculture or the culture as whole along with any belief systems of ideology underlying such consistencies.

major depressive disorder A disorder in which a person will have experienced five or more of the following symptoms for at least 2 weeks: depressed mood or irritable mood most of the day; decreased interest in pleasurable activities; changes in weight, or perhaps failure to make necessary weight gains in adolescence; sleep problems; psychomotor agitation or retardation; fatigue or loss of energy; feelings of worthlessness or abnormal amounts of guilt; reduced concentration and decision-making ability; and repeated suicidal ideation, attempts, or plans of suicide.

management of the household All the planning, problem solving, and activities adults undertake in order to take care of themselves and others who are entrusted to their care.

managerial resourcefulness Flexible, creative problem solving in the workplace, particularly when facing new problems and changing conditions.

marital companionship Leisure activities shared by a married couple.

marital conflict Disagreement between partners in a marital relationship, often over opposing goals, needs, values, and the control of resources.

marriage The relationship that exists between two people who are in a consensual and contractual relationship recognized by law.

masculinity Gender traits associated with being instrumental and agentic (e.g., having leadership abilities, being assertive, taking control).

matched groups Two or more groups who are similar on many dimensions; in experimental research often one group of participants receives some type of treatment or experimental intervention but the other group does not.

matched groups sampling Two or more groups of participants who are similar on many dimensions are selected as the sample for an experiment. The effects of different treatments or manipulations are determined by comparing the behavior of these groups.

matching The infant and the caregiver are involved in similar behaviors or states at the same time.

meaning making The psychological system that seeks out information, integrates information from many sources, and evaluates experiences as positive or negative, encouraging or threatening.

memory Complex capacity that includes recognizing something similar to something one has seen or experienced in the past, holding information in mind for a brief period before using it, and recalling information as needed.

menopause The natural cessation of menstruation, usually occurring in the fifth decade of life; one aspect of the close of a woman's fertility.

mental image A form of representational thought that involves the ability to hold the picture of a person, object, or event in one's mind even in the absence of the stimulus itself.

mental operation (plural: mental operations) A transformation—carried out in thought rather than action—that modifies an object, event, or idea.

mercy killing Taking a person's life in order to end their suffering. In our society, this is considered to be murder.

mesosystem The interrelations among two or more settings in which the developing person actively participates (e.g., for a child, the relations between home, school, and neighborhood peer groups; for an adult, between family, work, and social life).

metabolism A collective term for all the chemical processes that take place in the body: in some (catabolic), a complex substance is broken down into simpler ones, usually with the release of energy; in others (anabolic), a complex substance is built up from simpler ones, usually with the consumption of energy.

metacognition Thinking about one's own thinking, including what individuals understand about their reasoning capacities and about how information is organized, how knowledge develops, how reality is distinguished from belief or opinion, how to achieve a sense of certainty about what is known, and how to improve understanding.

microsystem A pattern of activities, roles, and interpersonal relations experienced by the developing person in a given setting with specific physical and material characteristics.

mirror neuron system A coordinated network of neural areas that underlies a person's ability to observe and then recreate the actions of others as well as to understand the emotions and intentions of others.

miscarriage Spontaneous termination of a pregnancy.

mismatch The infant and caregiver are not involved in the same behaviors or states at the same time.

mistrust A sense of unpredictability in the environment and suspicion about one's own worth. Experiences with mistrust are most critical during infancy.

model In social learning theory, the person being observed.

modeling In social learning theory, the process of observing a person.

monozygotic twins Twins who develop from a single fertilized egg. These twins have identical genetic characteristics.

moral development The acquisition of the principles or rules of right conduct and the distinction between right and wrong.

moral exemplars People who have dedicated themselves to improving the lives of others.

moral identity The sense in which a person defines himself or herself in moral terms and evaluates his or her behavior against moral standards that represent an integration of parental socialization about caring for others, an appreciation for the cultural and social contexts of moral actions, and experiences that have required moral action.

moral intuition An emotional or affective aspect to morality; a more primitive, immediate, almost automatic system that evaluates experiences as positive or negative, without going through steps of searching for more information or weighing evidence.

morality Conforming to rules of right or virtuous conduct that involves conceptions of the rights, dignity, and welfare of others.

moral reasoning (1) A cognitive aspect to morality that is based on assessments of intention, fairness, justice, and social obligation. (2) The ability to use logic in order to evaluate what is right and wrong; this capacity matures along with other cognitive abilities from childhood to adulthood.

moratorium An identity status in which people are involved in ongoing exploration and experimentation; typically an active, open time for gathering information and discovering how one fits in certain roles.

motor development All the changes in a child's ability to control, coordinate, and direct movement, including movement of the eyes and head, as well as movement of fingers, arms, legs, and torso.

multiply determined In psychosexual theory, behaviors that may appear to be somewhat unusual or extremely intense—a single behavior expresses many motives, some of which the person can recognize and control and others that are guided by unconscious thought.

mutation The change in the structure of a gene that can be passed along to the next generation.

mutuality The ability of two people to meet each other's needs and to share each other's concerns and feelings.

mutuality among peers Empathic awareness of one another, understanding of self and other, and the ability and willingness to regulate one's needs in order to respond to the needs of one's partner.

mutuality with the caregiver The ability of the caregiver to understand and meet the infant's needs; and the infant's understanding that his or her needs will be met.

myelin A substance that forms around the axons of some neurons, acting as an insulator that speeds signals from one neuron to the next.

myelination The formation of a soft, white, fatty material called myelin around certain nerve axons to serve as an electrical insulator that speeds nerve impulses to muscles and other effectors.

narcissistic Extremely self-absorbed and self-loving.

narcissistic people Adults who devote their energy and skills to the sole end of self-aggrandizement and personal satisfaction.

naturalistic observation See ethnography.

natural selection A process whereby those individuals best suited to the characteristics of the immediate environment are most likely to survive and reproduce.

negative communication Verbal and nonverbal negative expressions and hostile put-downs.

negative identity A clearly defined self-image that is contrary to the cultural values of the community.

network Individuals in significant relationships who interact with each other as well as with the target person.

neural plasticity All the changes in the brain's neural pathways that occur as a result of learning and experience. Also, the ways the brain compensates for injury by making use of alternate resources.

neural tube The tube formed during the early embryonic period that later develops into the brain, spinal cord, nerves, and ganglia.

neuron (plural: neurons) A nerve cell with specialized processes; the fundamental functional unit of nervous tissue.

neuroticism A personality dimension consistently associated with discouragement, unhappiness, and hopelessness. Neuroticism includes such qualities as anxiety, hostility, and impulsiveness.

neurotransmitters Chemicals that influence how the nerves grow, how they respond to stimulation, and whether they result in the firing or the inhibition of firing of the neurons.

nonparental care Child care arrangements in which infants and toddlers are taken care of by persons who are not their parents. Center-based care includes day care centers, Head Start programs, preschool, prekindergarten, and other early childhood programs.

norm of reaction A pattern of possible phenotypes that are likely to be observed under different environmental conditions.

norm of reciprocity The cultural norm that you are obligated to return in full value what you receive.

norms Collective expectations or rules for behavior held by members of a group or society.

novice A person who has just started learning something. The first stage of a developmental progression to acquiring a new skill.

nuclear family A household grouping that includes one or two parents and their children.

nursing home A facility that provides housing, food, nursing care, and rehabilitation for people who have severe functional limitations as a result of illness, surgery, aging, or advanced dementia.

obesity A condition of extreme overweight.

objective observations No prior bias; based solely on facts or what is taking place.

object permanence A scheme acquired during the sensorimotor stage of development, in which children become aware that an object continues to exist even when it is hidden or moved from place to place.

object relations The component of ego development that is concerned with the self, self-understanding, and self–other relationships.

object relations theory A modern adaptation of psychoanalytic theory that places less emphasis on the drives of aggression and sexuality as motivational forces and more emphasis on human relationships as the primary motivational force in life.

objective Based on facts and not influenced by personal feelings, interpretations, or prejudices.

observation A research method in which behavior is watched and recorded.

observation of models A mechanism for learning; the process in which a person watches and imitates others.

obsessions Persistent repetitive thoughts that serve as mechanisms for controlling anxiety.

obsessive-compulsive disorder An anxiety disorder that is characterized by recurrent, unwanted thoughts (obsessions) and/or repetitive behaviors (compulsions).

obsessive reminiscence Reminiscence that suggests an inability to resolve or accept certain past events and a persistent guilt or despair over these events.

occupational hazards Potential physical and psychological risks associated with the workplace, including exposure to toxins, work-related injuries, and exposure to diseases, reproductive hazards, and working conditions that have negative psychological consequences.

Oedipal complex In psychosexual theory, a conflict that results from ambivalence surrounding heightened sexuality during the phallic stage. The son has a strong, sexualized attraction to his mother, and his father becomes a fantasized rival. See Electra complex for girls.

old-old Among the very old, those who have suffered major physical or mental decrements.

openness to experience A personality characteristic that includes curiosity, imaginativeness, and enthusiasm for novelty.

operation (plural: operations) In Piaget's theory, an action that is performed on an object or a set of objects.

operational definition In research, the way an abstract concept is defined in terms of how it will be measured.

operationalize To translate an abstract concept into something that can be observed and measured.

optimal functioning What a person is capable of doing when motivated and well prepared.

optimism A belief that one's decisions will lead to positive consequences and that situations will turn out well.

oral stage In psychosexual theory, a period of life in which the mouth is the site of sexual and aggressive gratification, typically during the first year of life.

organic brain syndromes Disorders involving memory loss, confusion, loss of ability to manage daily functions, and loss of ability to focus attention.

out-group A group that competes with one's own group; contrasted with in-group.

overregularization (verb: overregularize) In language acquisition, the tendency to use a grammar rule for the formation of regular verbs or nouns when one cannot remember the irregular form. As a child's vocabulary grows, the need to apply the rule to unfamiliar words declines.

ovum An egg; the female germ cell.

oxytocin A hormone that plays a key role in social attachment, produces a general sense of calm relaxation, reducing wariness and increasing approach behavior.

pace of life The busyness of life, including activity, leisure, and rest, which is shaped by work, family, personality, and environmental contexts.

parental alienation A psychological condition in which a child becomes strongly allied with one parent and rejects a relationship with the other parent, without legitimate justification; often a result of one parent's manipulation of the image of the other parent.

parental attachment The relationship of a child to his or her parents characterized by different possible levels of stability and security.

parental identification A developmental process through which a child incorporates the values, beliefs, and behaviors of the parent.

parenting The rearing of children.

parenting alliance The capacity of a spouse to acknowledge, respect, and value the parenting roles and tasks of the partner.

participant observation Observation in which the researcher actively engages in interactions with other members of the setting.

passive euthanasia Withholding treatment or removing life-sustaining nourishment and breathing aids for the dying person with the result that death occurs more quickly than if these procedures were continued.

patterns of bereavement Five categories of adjustments an individual may make to the loss of a loved one that include common grief, resilient, chronic grief, chronic depression, and depressed-improved.

peer approval Receiving positive reactions from peers and inhibiting behaviors that evoke peer ridicule in order to fit in with one's social group.

peer group membership Inclusion in a group of people of similar age, grade, or status.

peer play Play interactions with one's peers that provide opportunities for physical, cognitive, social, and emotional development.

peer pressure Expectations to conform and commit to the norms of one's peer group.

peer review The process in which other professionals read and critically evaluate a researcher's materials before they are published.

persistent vegetative state State in which a person's brainstem functions to continue to maintain heartbeat and respiration even when there is no cortical functioning.

personal choice When children recognize a domain of personal freedom in decision making that is not guided by adult authority and regulations but by the child's own preferences.

personal fable An intense investment in one's own thoughts and feelings and a belief that these thoughts are unique.

personality A pattern of thoughts, feelings, and actions that are characteristic of a person across situations.

person–environment interaction Ongoing experiences between the individual and the physical and social environment that includes the family, work setting, neighborhood, and larger political community.

person in the setting In developmental systems theory, the focus of analysis.

perspective taking The ability to consider a situation from a point of view other than one's own.

phallic stage In psychosexual theory, a period of heightened genital sensitivity in the absence of the hormonal changes that accompany puberty, typically starting during the third year of life and lasting until the child is 6.

phases of career decision making A model for choosing an occupation and making occupation-related decisions; includes seven stages: exploration phase, crystallization phase, choice phase, clarification phase, induction phase, influence phase, and integration phase.

phenotype The observable characteristics that result from the interaction of a particular genotype and a particular environment.

phonemic awareness Knowing the sound of letters and being able to hear these sounds as one reads.

physical changes of aging Multidimensional and variable changes that affect all individuals as they age, caused by an interaction of genetic, environmental, social, and lifestyle factors.

physical culture Encompasses the objects, technologies, structures, tools, and other artifacts of a culture.

physical state In self-efficacy theory, the state of arousal or excitement that provides information as one makes a judgment whether one is likely to succeed or fail in a certain task.

physician-assisted suicide The administration of a lethal dose of some medication by a physician or arranging for a terminally ill patient to administer his or her own lethal dose of medication using a suicide machine.

placenta The vascular organ that connects the fetus to the maternal uterus and mediates metabolic exchanges.

plagiarism Using someone's words or ideas without giving them credit or taking credit as if they were one's own.

plasticity (1) The capability of being shaped and molded. (2) The capacity for continuous alteration of the neural circuits and synapses of the living brain and nervous system in response to experience or injury that involves the formation of new circuits and synapses and the elimination or modification of existing ones.

play companions The people who play with a child, including parents, siblings, peers, and child care professionals.

pleasure principle From psychosexual theory, the instinctive drive to seek pleasure and avoid pain that originates and is expressed in the id.

point of view about death A considered and/or evaluated perspective about death, including the death of others and oneself.

population All units for potential observation.

positivism An approach to the study of human behavior that seeks causal relationships among factors, with the goal of trying to predict outcomes.

positivity bias The tendency to view one's romantic partner in an overly positive light, thereby making one feel he or she has found the absolutely perfect partner, and making the partner feel valued and cherished.

postconventional level Stage III of Kohlberg's moral reasoning theory, bringing an awareness that rules and laws are a product of social, cultural, and political processes; individuals can evaluate the fairness and appropriateness of these rules and laws based on their own values and the social conditions.

postformal reasoning The integration of abstract, logical-mathematical reasoning with the special emotional and social demands of the circumstances.

postformal thought A qualitatively new form of thinking that emerges after formal operational thought which involves a higher use of reflection and the integration of contextual, relativistic, and subjective knowledge.

postpartum depression A period of sadness that may be experienced by the mother after giving birth, which appears to be related to hormonal activity.

post-traumatic stress disorder A mental disorder that occurs after a traumatic event outside the range of usual human experience, characterized by symptoms such as reliving the event, reduced involvement with others, and manifestations of autonomic arousal such as hyperalertness and exaggerated startle response.

poverty Commonly understood as the condition of having little money and few material possessions. Since poverty is defined at the family level and not the household level, the poverty status of the household is determined by the poverty status of the householder. Households are classified as poor when the total income of the householder's family is below the appropriate poverty threshold. (For nonfamily householders, their own income is compared with the appropriate threshold.) The income of people living in the household who are unrelated to the householder is not considered when determining the poverty status of a household, nor does their presence affect the family size in determining the appropriate threshold. The poverty thresholds vary depending on three criteria: size of family, number of related children, and, for one- and two-person families, age of householder.

poverty threshold The minimum cash income needed to support a person or a family in meeting basic needs of daily living.

power assertion A discipline technique involving physical force, harsh language, or control of resources.

pragmatics The relationship of the social setting to the production and interpretation of language. Vocabulary, grammar, and pragmatics combine to form communication.

precocious puberty Changes in pubertal maturation that occur before the age of 8 for girls and before the age of 9 for boys.

preconscious From psychosexual theory, a part of the mind just below conscious awareness from which memories and emotions can be recalled or retrieved.

preconventional level Stage I of Kohlberg's moral reasoning theory in which children judge an action as morally justifiable based on the immediate consequences of the behavior and the approval of powerful authority figures.

preconventional morality In Kohlberg's stages of moral reasoning, the most immature form of moral judgment. Moral decisions are based on whether the act has positive or negative consequences, or whether it is rewarded or punished.

prediction Declaration in advance, usually with precision of calculation.

prefrontal cortex The area of the brain that appears to be responsible for supporting the capacities of executive functions including deriving abstract concepts, rules, and generalizations from sensory and motor experiences and applying them in new situations.

pre-literacy Describing the skills and knowledge necessary before a child can learn to read independently.

preoccupied attachment An outcome of attachment in which a person has a positive model of others and a negative model of the self.

preoperational thought In Piaget's theory of cognitive development, the stage in which representational skills are acquired.

pretense Imagination or make-believe.

pride A feeling of satisfaction derived from success in one's own achievements or the achievements of others with whom one is closely associated.

primary narcissism In psychosexual theory, a process in which the sense of ego emerges as psychic energy and is directed toward the self: the sense of self is born out of self-love, an enthusiasm and excitement for one's body, one's experiences, and one's emerging sense of agency.

primary process thought From psychosexual theory, the quality of unconscious thought derived from the pleasure principle that is characteristic of the id and is observed in dreams. This kind of thinking lacks many of the constraints of time, social convention, and shared meaning.

primary sex characteristics Physical structures in males and females directly related to the reproductive capacity.

prime adaptive ego qualities Mental states that form a basic orientation toward the interpretation of life experiences; new ego qualities emerge in the positive resolution of each psychosocial crisis.

principal of care A sense of duty or obligation to help someone who is in need.

privacy Keeping an individual's confidential information secret, especially in a research study.

private self Refers to a person's inner uniqueness and unity and the subjective experience of being the originator of one's thoughts and actions and of being self-reflective.

process An ongoing operation or activity, not directly observable, that takes place in small increments over time and leads to a natural transformation.

processing load In problem solving, the number of domains of information called into play and the amount of work necessary to select response strategies.

processing speed The time it takes to identify a stimulus and figure out its meaning.

prohibitive moral judgment (plural: prohibitive moral judgements) A judgment involving a conflict between violating a law and breaking a promise in order to achieve some other goal.

prompting Urging a child to say more about an incomplete expression.

prosocial moral judgment (plural: prosocial moral judgements) A judgment involving a conflict between doing something helpful for someone else and meeting one's own needs.

prospective memory Memory about events or actions taking place in the future.

proteome Constellation of all proteins in a cell. Unlike the relatively unchanging genome, the dynamic proteome changes from minute to minute in response to tens of thousands of intra- and extracellular environmental signals. A protein's chemistry and behavior are specified by the gene sequence and by the number and identities of other proteins made in the same cell at the same time and with which it associates and reacts. Thus, at the cellular level, genetic and environmental information are continuously interacting to influence the functions of the cells.

pruning A process of sculpting synapses, in which infrequently used connections drop away.

psychological system Includes those mental processes central to the person's ability to make meaning of experiences and take action. Emotion, memory and perception, problem solving, language, symbolic abilities, and orientation to the future all require the use of psychological processes. The psychological system provides the resources for processing information and navigating reality.

psychosocial Of or pertaining to the interaction between social and psychological factors.

psychosocial approach A process that seeks to understand development as a product of interactions among biological, psychological, and societal processes.

psychosocial crisis A predictable life tension that arises as people experience some conflict between their own competencies and the expectations of their society.

psychosocial evolution The contribution of each generation to the knowledge and norms of society.

psychosocial moratorium A period of free experimentation before a final identity is achieved.

psychosocial theory A theory of psychological development that proposes that cognitive, emotional, and social growth are the result of the interaction between social expectations at each life stage and the competencies that people bring to each life challenge.

pubertal status The extent to which physical markers have emerged in the transition to adult reproductive and sexual maturity.

puberty The period of physical development at the onset of adolescence when the reproductive system matures.

public self The many roles that one plays and the expectations that social reference groups, including family members, neighbors, teachers, friends, religious groups, ethnic groups, and even national leaders, have for one's behavior.

punishment A penalty or negative experience imposed on a person for improper behavior.

purpose The ability to imagine and pursue valued goals.

qualitative inquiry An approach to the study of human behavior that tries to understand the meanings, motives, and beliefs underlying a person's actions.

quasi-experimental Treatment in a human development study that is not controlled by the experimenter but was the result of some pattern of life events.

quasi-experimental study A study in which the assignment of participants to treatment was not controlled by the experimenter but was a result of some pattern of life events.

question-asking Using inquiry to gather information, accomplish goals, or clarify a situation.

quickening Sensations of fetal movement, usually beginning during the second trimester of fetal growth.

radius of significant relationship The groups of important people in one's life. The breadth and complexity of these groups change over the life span.

random sample A sample in which each person in a given population has an equal chance of being included.

random sampling A method for choosing the sample for a study in which each member of the population under investigation has an equal chance of being included.

range of applicability The nature of the concepts and principles that a theory is trying to explain.

rapport Conveying a feeling of trustworthiness and acceptance in an interview or in a counseling setting.

reaction range The range of possible responses to environmental conditions that is established through genetic influences.

reaction time The interval between the onset of a stimulus and a behavior in response.

reactive With regard to surveys, the quality of creating attitudes where none existed before.

reactive nature of surveys The ability of some surveys to create attitudes where none existed before.

reactivity A child's threshold for arousal, which indicates the likelihood of becoming distressed.

readiness A time when a child's physical, cognitive, social, and emotional maturation is at a level to undertake new learning or to engage in a more complex, demanding type of activity or relationship.

reading fluency The accuracy and speed with which one can read words in a text.

reality principle In psychosexual theory, a principle in which the ego protects the person by waiting to gratify id impulses until a socially acceptable form of expression or gratification can be found.

receptive language The ability to understand words.

reciprocal role Social roles that are partly defined by the other roles that support them such as the student and the teacher, the parent and the child, and the salesperson and the customer.

reciprocity A scheme describing the interdependence of related dimensions, such as height and width or time and speed.

reference group (plural: reference groups) A group with which an individual identifies and whose values the individual accepts as guiding principles.

reflex(plural: reflexes) An involuntary motor response to a simple stimulus.

regression In psychosexual theory, a defense mechanism where a person reverts to an earlier form of drive satisfaction, immature forms of relationships with others, lower moral standards, or more simplistic ways of thinking and solving problems.

rejection Refusal to accept someone in a social group.

rejectivity The unwillingness to include certain others or groups of others in one's generative concerns.

relational paradigm In contemporary psychoanalytic theory, the view that humans have basic needs for connection, contact, and meaningful interpersonal relationships and that the self is formed in an interpersonal context and emerges through interactions with others. Maturity requires the achievement of a sense of vitality, stability, and inner cohesiveness formulated through interpersonal transactions. Psychopathology or dysfunction arises when a person internalizes rigid, rejecting, or neglectful relational experiences and then uses these internalizations to anticipate or respond to real-life social encounters.

reliable With regard to tests, the quality of being repeated consistently. For example, a person who takes the same test on two consecutive days and earns approximately the same score both times has taken a reliable test.

reliability The consistency of a test in measuring something.

remarriage Marrying two or more times.

reminiscence The process of thinking or telling about past experiences.

repair (plural: repairs) See communication repairs.

repeatable In research, it is important that others carry out a similar investigation and observe the same results as the original investigator. For this to occur, the original investigator must carefully define all the procedures and equipment used, describe all the essential characteristics of the participants (e.g., age, sex, and social class background), and describe the setting or situation where the observations were made.

representational skills Skills learned in the preoperational stage—including mental imagery, symbolic play, symbolic drawing, imitation, and language—that permit the child to represent experiences or feelings in a symbolic form.

repression In psychosexual theory, a defense mechanism where unacceptable impulses are pushed into the unconscious.

repudiation Rejection of roles and values that are viewed as alien to oneself.

reputational identity Identity characteristics assigned to someone by those in their environment (such as a school) that is derived from their being associated with a crowd in the setting.

research design A process that outlines an empirical study, focusing on the approach to selecting a sample, the methods used to gather information, the design for studying change, and the techniques to analyze the data.

reserve capacity A person's resources to protect themselves from illness or recover from illness or stress, especially as they age.

resilience The capacity to recover from stress, or the ability to withstand the effects of stressors that are typically associated with negative outcomes.

resilient Able to withstand or recover quickly from difficult conditions.

resistant attachment A form of insecure attachment in which the child is anxious about exploring the environment, even when the mother is present, shows distress and anxiety in the Strange Situation when the mother is absent, and may be ambivalent about being comforted even after the mother returns.

resources Skills, talents, wealth, or other goods that can be used as needed.

restoration-oriented coping Refers to finding ways to master the practical challenges of the loss of a loved one in order to make meaning of the death and move along in one's life.

retirement A societal and psychological construct in which an individual ceases to work year-round full time, often withdrawing from the formal structure of work.

retirement anxiety Apprehensions that adults have as they anticipate retirement.

retrospective study Research that asks the participants to report on experiences from an earlier time in their lives.

reversibility A scheme describing the ability to undo an action and return to the original state.

rites of passage A ceremony or ritual associated with an important transition in a person's life.

ritual A formal and customarily repeated act or series of acts.

role A set of behaviors with some socially agreed-upon functions and for which there exists an accepted code of norms, such as the role of teacher, child, or minister.

role compatibility When partners in a relationship approach situations in a manner that works well, their behaviors and responses complement one another.

role conflict The state of tension that occurs when the demands and expectations of various roles conflict with each other.

role enactment Patterned characteristics of social behavior that one performs as a result of being in a specific role.

role expectations Shared expectations for behavior that are linked to a social role.

role experimentation The central process for the resolution of the psychosocial crisis of later adolescence which involves participation in a variety of roles before any final commitments are made.

role overload The state of tension that occurs when there are too many role demands and expectations to handle in the time allowed.

role reversal Assuming the behaviors of a person in a reciprocal role, as when a child acts toward his or her parent as a parent.

role sequencing The order of entry into new roles and age-related role transitions often based on normative expectations of members of one's ethnic group.

role spillover The state of tension that occurs when the demands or preoccupations about one role interfere with the ability to carry out another role.

role strain The conflict and competing demands made by several roles that the person holds simultaneously.

romantic love A form of love that combines passion and commitment; an exhilarating, emotional, and preoccupying experience of affection and attachment to the loved object.

rule (plural: rules) Principle or regulation governing conduct, action, procedure, or ritual.

sampling A method of choosing participants in a study.

scaffolding A process through which a child and an adult attempt to arrive at a shared understanding about a communication, at which point the adult interacts so as to expand or enrich the child's communicative competence.

scheme (plural: schemes) In Piaget's theory, the organization of actions into a unified whole, a mental construct.

school readiness When a child's physical, cognitive, social, and emotional maturity are at a level to undertake the rigors of formalized schooling.

scientific process A set of techniques for acquiring new knowledge, investigating questions of interest, and modifying or correcting previous knowledge.

secondary process thought In psychosexual theory, a reality-oriented thinking; a logical, sequential thinking.

secondary sex characteristics The physical characteristics other than genitals that indicate sexual maturity, such as body hair, breasts, and deepened voice.

secular growth trend A tendency, observed since approximately 1900, for more rapid physical maturation from one generation to the next, probably as a result of favorable nutrition, increased mobility, and greater protection from childhood diseases.

secure attachment Infants actively explore their environment and interact with strangers while their mothers are present. After separation, the babies actively greet their mothers or seek interaction. If the babies were distressed during separation, the mothers' return reduces their distress, and the babies return to exploration of the environment. In adulthood, this is an attachment outcome in which a person has a positive model of the self and of others.

selection The process in which adolescents form relationships with other adolescents who share certain common interests, values, or preferences.

selection forces Adolescents seek out friends who will support their involvement or their resistance to the use of alcohol and drugs as part of a more general pattern of behavior.

self-acceptance The product of the positive feelings that come from expressing and trusting one's ideas and feelings; and from the acceptance one receives from others.

self-actualization A motive that urges the person to make optimal use of his or her full potential to become a more effective, creative participant in daily life.

self-control For toddlers, the ability to comply with a request, modify behavior according to the situation, initiate or postpone action, and behave in a socially acceptable way without having to be guided or directed by someone else.

self-efficacy A sense of confidence that one can perform the behaviors that are demanded in a specific situation.

self-esteem The evaluative dimension of the self that includes feelings of worthiness, pride, and discouragement.

self-evaluation The ability to assess one's own abilities and skills.

self-fulfilling prophecy False or inaccurate beliefs can produce a reality that corresponds with these beliefs.

self-insight An understanding and awareness of one's true nature.

self-monitoring children Some children appear to monitor their social environment more self-consciously than others. High self-monitoring children are more aware of the emotional and nonverbal behavior of others and make more use of social information to evaluate and regulate their own behavior than low self-monitoring children.

self-presentation bias Research participants may present themselves in the way they want the interviewer to see them.

self-regulation Behavior inhibition in response to stimuli.

self-regulatory plan (plural: self-regulatory plans) A strategy for achieving one's goals, including techniques for managing internal emotional states, creating a plan, and putting the plan into action.

self-sufficiency The state of making independent decisions, taking responsibility for one's actions, and achieving a degree of financial independence.

self-theory An organized set of ideas about the self, the world, and the meaning of interactions between the self and the environment.

semantic memory Recall of basic knowledge, such as the meaning of words like "vegetable," "democracy," or "insect."

semiotic thinking The understanding that one thing can stand for another.

sensation seeking A tendency to pursue activities that are novel, thrilling, and exciting.

sense of coherence A process in which one seeks to find an integrative thread that makes sense of the life one has led without belaboring past mistakes.

sense of control A feeling that one has the authority or power to direct one's behavior in various aspects of one's life, such as selecting one's leisure activities or choosing when to retire. In older adults, a sense of control is associated with life satisfaction.

sensitive period (plural: sensitive periods) A span of time during which a particular skill or behavior is most likely to develop.

sensitivity (of caregiver) Attentiveness to an infant's state, accurate interpretation of the infant's signals, and well-timed responses that promote mutually rewarding interactions.

sensorimotor adaptation Infants use their reflexes to explore their world, and they gradually alter their reflexive responses to take into account the unique properties of objects around them. This provides the basis for sensorimotor intelligence.

sensorimotor intelligence In Piaget's theory of development, the first stage of cognitive growth, during which schemes are built on sensory and motor experiences.

sensorimotor play Sensory exploration and motor manipulation that produce pleasure.

sensory register The neurological processing activity that is required to take in visual, auditory, tactile, and olfactory information.

separation anxiety Feelings of fear or sadness associated with the departure of the object of attachment.

sex Refers to biological features or distinctions of men and women that are determined by chromosomal information.

sex linked Genetic material that is located on the 23rd chromosome.

sex-linked characteristics Characteristics for which the allele is found on the sex chromosomes.

sex segregation A characteristic of young children's friendships where boys and girls tend to choose play companions of their own sex.

sexual motivation A person's interest in initiating sexual behaviors.

shame An intense emotional reaction to being ridiculed or to a negative self-assessment.

short-term memory The working capacity to encode and retrieve five to nine bits of information in the span of a minute or two. This is the scratch pad of memory that is used when someone tells you a telephone number or gives you his or her address.

sign (plural: signs) Something that represents something else, usually in an abstract, arbitrary way, for example, a word for an object.

significant relationship Important relationships that provide opportunities for great depth and intimacy and which allow age-related demands on individuals to be communicated.

similarity bias The tendency to exaggerate perceptions of similarity between partners, thereby increasing feelings of closeness and being understood.

skill (plural: skills) An ability to do something competently in a particular area that combines knowledge, practice, and training.

skill care facility See nursing homes.

small for gestational age (SGA) Fetus who does not weigh as much as a normal fetus of the same age. These fetuses are at greater risk for health problems than those who are born prematurely but are of average weight for their gestational age.

SOC model A model of adaption that requires the integration of three processes: selection, optimization, and compensation.

social anxiety A fear of being watched, judged, and criticized in social situations.

social clock Expectations for orderly and sequential changes that occur with the passage of time as individuals move through life.

social cognition Concepts related to understanding interpersonal behavior and the point of view of others.

social cognitive neuroscience The field of study that explores the neurological processes associated with the ways we perceive social information and reason about others. It is premised on the idea that articulating the biological, cognitive, and social levels of analysis contribute to more comprehensive explanations of human mind and behavior. While higher order metacognitive processes affect how we consciously operate in social interactions, automatic and unconscious mechanisms also account for much social interaction.

social comparison Comparing oneself to others in a particular social environment.

social competence The skills involved in one's ability to form and maintain positive relationships with others.

social construction In the study of gender, the view that gender differences are a product of cultural scripts and contextualized social expectations.

social controls Guiding models and influences that encourage or restrict one's behavior; common sources of influence include parents, friends, authority figures, and religious values and beliefs.

social conventions Socially accepted norms and regulations that guide behavior.

social culture Encompasses the norms, roles, beliefs, values, rites, and customs of a culture.

social evolutionary theory A theory that emphasizes reproductive potential and reproductive investment in the selection of a desirable partner.

social expectations The appraisals and beliefs of significant others about what is valued or desirable that impact a person's performance.

social identity The aspect of the self-concept that is based on membership in a group or groups and the importance and emotional salience of that membership.

social integration Being comfortably involved in meaningful interpersonal associations and friendship relations.

socialization The process of teaching and enforcing group norms and values to the new group members.

social learning theory A theory of learning that emphasizes the ability to learn new responses through observation and imitation of others.

social play Children joining with other children in some activity.

social pretend play Children who coordinate their pretense. They establish a fantasy structure, take roles, agree on the make-believe meaning of props, and solve pretend problems.

social referencing The process by which infants use facial features and verbal expressions as clues to the emotional responses of another person, often the mother, and as information about how to approach an unfamiliar, ambiguous situation.

social role A set of behaviors with some socially agreed-upon functions and for which there exists an accepted code of norms, such as the role of teacher, child, or minister.

social role theory The theory that emphasizes participation in varied and more complex roles as a major factor in human development.

social support The social experiences leading people to believe that they are cared for and loved, that they are esteemed and valued, and that they belong to a network of communication and mutual obligation.

societal system Includes those processes through which a person becomes integrated into society. Societal influences include social roles, rituals, cultural myths, social expectations, leadership styles, communication patterns, family organization, ethnic and subcultural influences, political and religious ideologies, patterns of economic prosperity or poverty and war or peace, and exposure to racism, sexism, and other forms of discrimination, intolerance, or intergroup hostility. The impact of the societal system on psychosocial development results largely from interpersonal relationships, often relationships with close or significant others.

sociobiology The scientific study of the biological basis of social behavior that focuses on practices within populations that increase the likelihood of certain genes surviving in subsequent generations of offspring.

socioeconomic level One's ranking based on a number of social and financial indicators, including years of education, occupation, and income.

socioeconomic status (SES) Refers to a combination of resources including income, education, and occupation.

socioemotional support Expressions of affection, care, respect, and esteem.

solicitude State of caring, attentiveness, and helpfulness.

solicitude versus shame A two-dimensional spectrum of cultural attitudes toward pregnant women. Solicitude is shown in the care, interest, and help of the pregnant woman and fetus. Shame is instilled through humiliation or separation of the pregnant woman. Combined with adequacy versus vulnerability, these attitudes create a matrix within which the birth culture of any society or subculture can be located.

solitary pretense Children are involved in their own fantasy activities, such as pretending that they are driving a car or giving a baby a bath.

speciation A process that contributes to biological diversity wherein a new species is established by breaking away from an earlier evolutionary lineage.

speed of processing The amount of time it takes to detect and interpret sensory stimuli.

sperm The male germ cell.

spermarche The production and release of sperm that can be detected in a boy's urine; typically happens late in the pubertal process.

stagnation A lack of psychological movement or growth during middle adulthood that may result from self-aggrandizement or from the inability to cope with developmental tasks.

statistically significant Pertaining to observations that are unlikely to occur by chance and that therefore indicate a systematic cause.

status offense Behavior that is criminalized for minors, such as running away or truancy, which would not be against the law for adults.

stigmatized death (plural: stigmatized deaths) People attributing someone's death to an immoral, illegal, or evil cause.

strange situation A standard laboratory procedure designed to study patterns of attachment behavior. A child is exposed during a 20-minute period to a series of events that are likely to stimulate the attachment system. Child and caregiver enter an unfamiliar laboratory setting; a stranger enters; the caregiver leaves briefly; and the caregiver and infant have opportunities for reunion while researchers observe child, caregiver, and their interactions.

stranger anxiety Feelings of fear or apprehension in the presence of unfamiliar people, especially during infancy.

stratified sampling A method for choosing the sample for a research study in which participants are selected from a variety of levels or types of people in the population.

statistical techniques During the final, evaluation phase of the scientific process, techniques that help determine the likelihood that observations could have happened by chance.

subculture (plural: subcultures) A cultural group within a larger group that may or may not have beliefs at variance with a larger cultural group.

sublimation In psychosexual theory, a process that channels the energy from impulses into activities that either symbolize the impulses or express them in a socially acceptable form.

substantive complexity The degree to which one's work requires thought, independent judgment, and frequent decision making.

successful agers Elderly individuals who are characterized by three interdependent features: they have a low risk of disease and disease-related disabilities; high mental and physical function; and active engagement with life.

sudden infant death syndrome A cause of infant death in which apparently healthy babies are put to bed and are later found dead with no clear explanation, even after autopsy.

superego In psychoanalytic theory, the mental function that embodies moral precepts and moral sanctions. The superego includes the ego ideal, or the goals toward which one strives as well as the punishing conscience.

superordinate group identity The members of a team or other group who bring their own individual racial /ethnic, cultural, or socioeconomic group identities to a situation and are willing to suppress their differences and work together for the success of the group.

surrogacy An alternative to biological reproduction in which a woman is implanted through one of a variety of methods and carries the fetus through the full gestational period at which time she releases the infant to the individual or couple who enlisted her participation.

survey research A means of collecting specific information from a large number of participants.

swaddling The practice of wrapping a baby snugly in a soft blanket, which is a common technique for soothing a newborn in many cultures.

symbol (plural: symbols) An object or image that represents something. A symbol can be an image that represents an object, such as "chair," or an object that represents a concept, such as a dove.

symbolic play Imaginative or pretend activities that express emotions, problems, or roles.

synchrony Infant and caregiver move from one state to the next in a fluid manner. Interactions of the infant and caregiver are rhythmic, well timed, and mutually rewarding.

system An entity—a cell, an organ, an individual, a family, or a corporation—that is composed of interdependent elements that share some common goals, interrelated functions, boundaries, and an identity.

systematic In a careful, orderly way. Scientists have a framework of questions that they strive to answer based on what is already known and what theories predict. They approach research by having clear objectives, carefully defining the purpose of their work, and describing the specific methods they will use.

systematic approach An approach that ensures research is done in a careful, orderly way by having clear objectives, carefully defining the purpose of the research, and the specific methods researchers will use to reach those objectives.

systematic observation A step of the scientific process that tests a theory by translating an abstract concept into something that can be measured and observed. Observations must be objective, repeatable, and systematic.

Taegyo A Korean set of practices that defines the behavior of pregnant women based on the belief that the fetus is able to feel what the mother feels.

tantrums In young children, sudden, uncontrollable outbursts of anger and frustration.

teachable moment A time when a person is most ready to acquire a new ability.

team play Sports or games played with a group that generally have complex rules and that provide a context for early learning about the skills and orientations that will apply to the world of work and to functioning in the family group.

telegraphic speech Two-word sentences used by children that omit many parts of speech but convey meaning.

temperament Innate characteristics that determine the person's sensitivity to various sense experiences and his or her responsiveness to patterns of social interaction.

teratogens Agents that produce malformations during the formation of organs and tissues.

testosterone A hormone that fosters the development of male sex characteristics and growth.

thanatology The field of science that addresses dying and death as well as the psychological mechanisms of coping with them.

theory A logically interrelated system of concepts and statements that provides a framework for organizing, interpreting, and understanding observations, with the goal of explaining and predicting behavior.

third gender A concept that expands our way of thinking about gender by including more options than just man and woman.

time In ecological systems theory, the period in which change among the systems occurs.

trajectory (plural: trajectories) In the life course, the path of one's life experiences in a specific domain, particularly work and family life.

transgendered Refers to people who do not identify with or present themselves as reflecting the sex they were born with and who move across or combine gender boundaries.

transient exuberance A rapid increase in the number of neurons, dendrites, and synapses that form in the brain during the first 2 years of life.

transition (plural: transitions) In the life course, the beginning or close of an event or role relationship. For example, work transitions might be getting one's first job, being laid off, and going back to school for an advanced degree.

treatment In an experiment, the set of experiences or information a group of participants receives.

triangulation Confirming a researcher's insights by looking at written documents about the setting, interviewing other informants, and sharing observations with other members of the research team.

tribute A gift, testimonial, compliment, establishment of a public monument, or good works in the name of a deceased person given in acknowledgment of gratitude or esteem.

trimester (plural: trimesters) A conceptualized period of pregnancy that lasts three months. There are three trimesters in a typical pregnancy.

trust An emotional sense that both the environment and oneself are reliable and capable of satisfying basic needs.

turning point A critical incident that brings about a significant change in commitment.

ultrasound A technique for producing visual images of the fetus in utero through a pattern of deflected sound waves.

unacknowledged mourners People whose grief over a death is not sanctioned or supported by the community.

unconscious Psychological processes that occur outside of awareness, including problem solving.

unwanted sexual attention Sexual attention that is perceived as threatening, embarrassing, or harmful.

usefulness/competence Personality dimension associated with well-being and high self-esteem through volunteer work, involvement with others, and a sense of purpose and structure in the use of time.

usual aging A state of typical aging in which individuals may be functioning well but are at high risk for disease, disability, and reduced capacity for functional independence.

uterus In the female reproductive system, the hollow muscular organ in which the fertilized ovum normally becomes embedded and in which the developing embryo and fetus is nourished and grows.

vagal tone A process through which changes in heart rate vary during changes in environmental conditions. Typically, when you breathe in, heart rate increases, and when you breathe out, heart rate decreases. Under conditions when a task requires attention and concentration, heart rate increases, which allows for adaptive mobilization of resources. When the situation becomes more intense or threatening, heart rate slows, leading to conservation of resources and the ability to achieve a more calm state. The vagal system contributes to regulation of arousal and reactivity and is considered to be a basic neural component of self-regulation, information processing, and emotion.

valid With regard to tests, the quality of actually measuring what the test intends to measure.

validity The extent to which a test measures what it is supposed to measure.

value (plural: values) A principle or quality that is intrinsically desirable.

vascular dementia A form of dementia that occurs when the blood vessels to the brain are blocked or narrow; the brain does not get the blood flow, oxygen, and nutrients needed for adequate functioning.

verbal persuasion Encouragement from others.

viability Reaching the stage of development in which a fetus is capable of living outside the uterus.

vicarious experience An experience achieved through the imagined participation in events that happen to another person.

vicarious reinforcement Through observing others, a person can learn a behavior and also acquire the motivation to perform the behavior or resist performing that behavior depending on what is observed about the consequences of that behavior.

visual acuity The ability to detect visual stimuli under various levels of illumination.

visual adaptation The ability to adapt to changes in the level of illumination.

visual tracking Following an object's movement with one's eyes.

vital marriage The partners enjoy spending time together; they resolve conflicts quickly, often using compromise; they are willing to make sacrifices for each other; and they have a satisfying, pleasurable sex life.

vocabulary All the words a person uses and understands.

volunteer With regard to research, an individual who agrees to participate in a study. One cannot compel a person to participate in research.

volunteerism Involvement in some form of volunteer service.

volunteer sampling Sampling in which participants for a study are selected from volunteers.

well-being The state of being happy, healthy, or prosperous.

white matter Myelinated axons that connect gray matter and carry messages between nerve cells and brain regions.

whole-brain death A technical definition of death with eight criteria that was developed in 1981 by the President's Commission for the Ethical Study of Problems in Medicine and Biomedical and Behavioral Research.

widowhood The stage of life one enters when one's spouse dies.

will The determination to exercise free choice and self-control.

wisdom A type of expert knowledge that reflects sound judgment and good advice in the face of high levels of uncertainty.

withdrawal General orientation of wariness toward people and objects.

withdrawn A path to peer rejection in which children are shy and self-conscious.

word (plural: words) A unit of language, consisting of one or more spoken sounds or their written representation, that functions as a principal carrier of meaning.

work A job or activity that a person does regularly, especially to earn money.

work-family facilitation Individual coping strategies and family-friendly attitudes and resources of the workplace that make it easier for employees to address pressing family demands within the scope of their daily work.

work/life balance A concept that reflects the ability to prioritize career ambitions and goals with lifestyle goals to achieve a sense of well-being and life satisfaction.

working memory A type of memory that uses attention to hold and manipulate information in the short term.

working model of attachment An infant's expectations of the behavior of their caregiver that is based on the quality of attachment.

workplace discrimination Practices that occur in the workplace that involve the unjust or prejudicial treatment of one person or group of people.

worldview A way of making meaning of the relationships, situations, and objects encountered in daily life in a culture.

young-old Among the very old, those who remain healthy, vigorous, and competent.

zone of proximal development The emergent developmental capacity that is just ahead of the level at which the person is currently functioning.

zygote The first phase of fetal development, when a single cell is formed from two gametes.
